# THE ELECTRICIAN:

1-9838

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

---

## VOLUME XXXVII.

FROM MAY 1, 1896, TO OCTOBER 23, 1896.

---

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1896.

# INDEX TO "THE ELECTRICIAN."

# VOL. XXXVII.

## General Alphabetical Index.

*Italic figures* denote that the subject-matter is in the "Leading Articles" or in the "Editorial Notes."

### A

Accidents (*Bankside: Boilers*) 589, (*Bedford*) 105, (*Berlin*) 785, (*City of London*) 389, (*Limburg*) 299, (*Northumberland Avenue*) 108, ("*Scotia*") 801
Acetylides of Copper and Silver, 337
Actinometry, Electro-chemical, 272
Air, Measurements of Electric Currents through: by Lord Kelvin, J. T. Bottomley, and Magnus Maclean, 763
Alloys, Electrical Resistance of: by Lord Rayleigh, 277
Alternating Currents, Measurement of very Large and of very Small: by A. Campbell, 285
Alternating and Continuous Currents, Combined: by Alexander Russell, 502. (*See also page 598*)
Alternating-Current Stations and High-Voltage Lamps: by H. W. Couzens, 352
Alternating-Current Machinery, Notes on some American, 18, 146, 487
Alternators, American, with Special Wave Form, *2*
Aluminium as a Material for Fuse-Wire, *33*
American Institute of Electrical Engineers (Council), 167
ANDERSON, E. W.:
Notes on Electric Cranes, 705
APPLEYARD, R.:
Adjustment of the Kelvin Bridge, 11
True Resistance, 403
Arc, Alternate-Current, Effect of Wave Form on: by J. Frith, 11, 227
Arc, Curious Behaviour of, when Current is suddenly Switched on, *208*, 321, *331*
**Arc Lamps—**
Arc Lighting Practice [A. Dow], 186
Archereau, Statue to, 816
Parallel-Carbon Lamps, 265
Public Lighting by Arc Lamps [A. Blondel], 14, 42
Arc, The Electric, the True Resistance of, *67* [Frith and Rodgers], 93. (*See also under* "Negative Resistance.")
Arcs and Wave Forms, *12*, *165*, 188, [Frith] 11, 217
Arc, Spectrum of, 469
Armature Discs, Notching Press for, 762
Armature Losses: by Otto T. Bláthy, 375, 474, 499, 530. (*See also pages 365*, 446, *497 and under* "Correspondence.")
Armatures, Faults in, A Practical Method of Detecting: by H. Tinsley, 822
Armatures, Grooved, Insulation of, 530
Armington and Sims Engine Company, The, 740, 773
ARNO, RICCARDO:
On Viscous Dielectric Hysteresis, 92
Artesian Wells, Electric Lighting by, 390
Atmospheric Electricity, Observations on: by C. Chree, 408
Audition, The Mechanism of, 367
Aurora Borealis, The, 469
Australia as a Field for Electric Supply: by J. A. Dawson, 215
Australia, Electric Lighting in: by H. J. Spencer, 545, 591

### B

Bacteria and Electricity, 34
Bankruptcy, Receivers in, *48*
Barbarisms of Science, *366*
BARNARD, A. S.:
Electricity Supply at 220 volts, 351
BARNETT, MAURICE:
The Evolution of the Storage Battery, 90
BAKER, J. MARK, BEETON, S., and TAYLOR, P.:
Experimental Tests on the Influence of the Shape of the Applied Potential Difference Wave on the Iron Losses of Transformers, 76, 110, (*Discussion*) 144
BARR, J. MARK, AND PHILLIPS, C.E.S.:
A New Vacuum Gauge, 822
BARSTOW, W.S.:
Local Developments of an American Central Station, 643
**Batteries (Primary)—**
Clark Cell, E.M.F. of, 138
Coehn Carbon Cell, 49
Hibbert Standard Cell, *298*, 320
**Batteries (Secondary)—**
American Theories *68*
Boese Accumulator, 377
Defects, *685*
Station, Large, 399
Storage Battery, The Evolution of, [Barnett] 90
BAXTER, WM.:
Efficiency of Railway Motors, 827
On the Multiplicity of Brushes in Large Generators, 739
BEATTIE, R., AND CLINKER, R. C.:
Magnetic Hysteresis in a Rotating Magnetic Field, 723
Beauchamp-Tower Platform for Search Lights, 137
Belfast, Electric Lighting in: by V. A. H. McCowen, 476. (*See also under* "Gas Engines")
Bell, "Turret" Motor, 806
Belt, A Monster, 405
BIRKELAND, M.:
Note on a Cathode Ray Spectrum, 791
Bismuth, Electrical Resistance of at −186°C: by Dr. J. A. Fleming, 267. (*See also pages 263*, *687*)
Bismuth, Transverse Effect in, 623
Blackpool Plant, The, *574*, 608, 613, 677, 742
BLATHY, OTTO T.:
Energy Losses in Electric Machines due to the Armature Current, 474. (*See also pages* 499, 530)
On the Dissipation of Energy caused by the Armature Currents in Electrical Machinery, 375
BLONDEL, ANDRÉ:
Public Lighting by Arc Lamps, 14, 42
Board of Trade (*Revised Rules re Unauthorised Undertakings*) 299
Boiler Explosion, German Definition of, 398
Boiler-making Dispute at the Thornycroft Works, *397*, 532
Boilers, Oil-fired, American Tests of, *366*
Boilers, Water-Tube, and Impure Water, *589*
Borough Electrical Engineer, The Troubles of, 656
BOSE, PROF. J. CHUNDER:
On a Complete Apparatus for the Study of the Properties of Electric Waves, 788
BOUVIER, E. L.:
A Telegraph Cable Attacked by White Ants, 662
Brighton Town Council *v.* Postmaster General, *264*
British Association (*Bristol*) 180, (*Dover*) 687, (*Grants*) 687, (*List of Papers*) 702, (*National Physical Laboratory*) 687, (*Popular Lecture*) 591, (*Prof. J. J. Thomson's Presidential Address*) *653*, (*Proceedings at Liverpool*) *685*, 700, (*Toronto*) 69, 105,
Brockie-Pell Arc Lamp (Limited), *431*
Brushes, Multiplicity of, in Large Generators: by Wm. Baxter, junr., 739
Brush Company's New Engine Works, 434
Brush Company, The, *749*
BURCH, G. J.:
The Capillary Electrometer in Theory and Practice, 380, 401, 435, 473, 514, 532
BURKE, J.:
Some Experiments with Rontgen Rays, 373

### C

Cables, Lock-Armoured, 632
Cable Specifications and Tests: by J. A. Jeckell, 376
Calcium Carbide (*Cost of Manufacture*) *136*, 143, 271, (*Foyers Plant*) 531, (*Niagara Plant*) 144
Callender's Cable and Construction Company, *431*
CAMPBELL, A.:
An Electric Frequency Teller, 437
The Measurement of very Large and of very Small Alternating Currents, 285
CAMPBELL, H. E.:
Modern Fly-Wheels, 728
Capillary Electrometer in Theory and Practice: by G. J. Burch, 380, 401, 435, 473, 514, 532. (*See also page 555.*)
Carbon, "Hard," 265
Carborundum (*Emery*) 106, (*Filaments*) 105, (*Metallurgical Utilisation*) 733, (*Output*) 561
Catalogue of Science, International, 266, *397*
Cathode Disc in the Crookes Tube, on a Rotational Motion of: by Prof. F. E. Nipher, 350
Cathode Ray Dust Figures, 367
Cathode Rays, Electrostatic Deflection of: by G. Jaumann, 343
Cathode Rays, 676, (*Spectrum: Birkeland*) 791
**Central Stations—**
Belfast, *103*, *497*, 476, 480
Brighton, Combined Alternate-Current Continuous-Current Supply at, 37
**Central Stations** (*Continued*)—
Colorado, 125
Continental, *589*, 614, 709
Data, 50
Gas Engine Stations, *34*, 138
Local Developments of an American Central Station [Barstow] 643
Newport, 604
Niagara Falls, 535
Salt Lake City, Three-Phase System at, 39
Shoreditch, 601
South Shields, 656
Val de Travers, 632
Wolverhampton (*Description*), 201
Woolwich, Combined Plant at, 580
Charging, A German Method of, *816*
Cheap Engineering, Costliness of, 232
CHESNEY, C. C.:
Electric Plant at the Montmorency Falls in Canada, 369
CHREE, C.:
Observations on Atmospheric Electricity at Kew Observatory, 408
Civil Engineers Institution of (*Council*) 167, (*Membership and Funds*) 243, (*Mode of Election*) 655, (*Secretary*) 298
Clark Cell, The E.M.F. of, 138
Coal Analyses, 69
Coal Mines, Precautions Necessary in the Use of Electricity in: by H. W. Ravenshaw, 218
Colchester System of Inviting Tenders, *530*
Colonial Electrical Engineering, *544*
COMBE, ABRAM:
Notes on the Introduction and Development of Rope Driving, 519
Company Law, *559*
Conductor, a Perfect, *The Engineer* and, 232
Congress, International Electrical, at Geneva, 35, 285, *397*, 500, (*Magnetic Unity*) 591, (*Photometric Units*) 592
Consulting *v.* Resident Engineers, *230*
Continental Electrical Engineering Practice, Some Distinctive Features of: by Kenelm Edgcumbe and E. J. Fox, 639
Corrosion of Iron by Raw Tar, 434
Cost of Electricity Supply: by Arthur Wright, 538
Cost of Electric Light and Power, 433
COTTRELL, S. B.:
Liverpool Overhead Railway, 766
Coupling, The Penson, for High-pressure Cables, 108
COUZENS, H. W.:
Alternating-Current Stations and High-Voltage Lamps, 352
Cranes, Notes on Electric: by E. W. Anderson, 705
CROMPTON, R. E. B.:
Electrically Operated Factories, 447

### D

Davy-Faraday Research Laboratory, 408
DAWSON, J. A.:
Australia as a Field for Electric Supply, 215
DEARLOVE, ARTHUR:
Lord Kelvin and Submarine Telegraphy, 226
Demonstrators' Salaries, *398*
Depreciation, 365
Dielectric Hysteresis, On Viscous: by Riccardo Arno, 92
Discharge of Cathode by Candle Flame, 531
Discharge, The Spark, Warburg's Researches on the Influence of Light on, 720
Dispersion, Electrical, in Liquids, 200, 720
Dispersion, Electromagnetic Theory of: by H. von Helmholtz, 404. (*See also page* 470)
DOW, A.:
Arc Lighting Practice, 186
DU BOIS and E. TAYLOR JONES:
Magnetisation and Hysteresis of certain kinds of Iron and Steel, 595
DUNLAP, O. E.:
Chlorate of Potash Works at Niagara Falls, 681
Niagara Falls Electric Light and Power Station, 535
Niagara Power House Extensions and the Buffalo Pole Line, 692
Power Transmission Developments at Niagara Falls, 514
Duodecimal System, The, 418. (*See also under* "Correspondence")
Duquesne Steel Works, Electrical Equipment of, 738

Digitized by Google

## E

EDGCUMBE, K., and FOX, E. J.:
Some Distinctive Features of Continental Electrical Engineering Practice, 639
EICKENRADT, F.:
The Use of Electricity on Board Ships, 576
Electrical Development and Finance Corporation, *467*
Electrical Engineers, Institution of, (*Alteration of the Articles of Association*) *135*, 141, 231, 332, (*Building Fund*) *444*, (*Student's Tour*) 720
Electric and Magnetic Research at Low Temperatures: by Prof. J. A. Fleming, 301
Electric Supply Data, 50
Electricity Supply at 200 volts: by A. S. Barnard, 351
**Electro-Chemistry—**
Acetylene as an Electrolyte, 821
Actinometry, Electro-chemical, 272
Aluminium, Copper-plating of, 138
Applied Electro Chemistry, *828*, [Swinburne] 663, 694, 759, 798
Calcium Carbide, *136*, 143, 144, 271, 531
Carbon, Electrolytic Dissolution of, 49, *210*
Carbon, Transformation of Energy of, into other available Forms [Reed] 598. (*See also page 510*)
Chlorate of Potash Works at Niagara Falls [Dunlap] 661
Electro-Chemical Company's Plant, 818
Gold in Sea-Water, Electrolytic Recovery of, 784
Jahrbuch der Electrochemie, 522
Niagara Electro-Chemical Company's Plant, 818
Nickel, Electrolytic, *498*
Percarbonate: Electrolytic Potassium, *783*, 792
Secondary Batteries (*American Theories*) *68*, [Barnett] 90, (*Beese*) 377, (*Defects*) *685*, 710
Soda and Potash Works at Niagara, 106
Sodium-Chloride, *752*
Specific Heat of Electrolytic Solutions, 137
Sulphuric Acid, Electrolytic Concentration of, *529*
Tanning, Groth Electric, 298
Tellurium, Electrical Separation of, from Copper Residues, 35
Tommassi Refining Apparatus, 200
Water, Electrolysis of, [Sokolow] 333
White Lead, Electrolytic, 272
Electromagnetic Theory: by Oliver Heaviside, 139, 279, 369, 558, 563, 753
Electrometer, A Dry Pile, 661
Electromotive Force in a Cell, On the Seat of: by Prof. O. J. Lodge, 755 (*see also* 694, 807)
Electroscope, A Three-Leaf, 433
Electrostatic Stress, Viscosity of Liquids when Submitted to, 819
Elementary Bodies, The Convertibility of, 719
ELSTER, J. and GEITEL, H.:
On the Influence of Light upon the Character of the Influence Machine Discharge, 123
Engine, A Five Crank, 697
Engineering Education: by E. H. Williams, 243
Engineering, Evolution in, *150*
Ewing Permeability Bridge, 41
EWING, Prof. J. A.:
Magnetic Testing of Iron and Steel, 115
Executions by Electricity in Ohio, 551
Exhibitions (*Berlin*) 3, (*Galvanometers*) 168, (*General*) 403, (*Horseless Carriages*) *34*, 52, 468, (*N.E.L.A., New York*) 23, 94, 125, (*Newcastle: 1887*) 751
Expert Witnesses, The, in the Welsbach Case, *1*
Extensions to Outlying Districts: by A. H. Gibbings, 506
Extravagance in the Electrical Business, The Era of, 500

## F

Factories, Electrically Operated: by R. E. B. Crompton, 447
Faults, "Breaking Down," 831
FISHER, W. C.:
The Crompton Potentiometer: its Use and Capabilities, 5, 269
Fittings, Artistic, 802
FITZGERALD, Prof. G. F.:
Lord Kelvin's Researches, 233
FLEMING, Prof. J. A.:
Electrical Resistivity of Bismuth, 267. (*See also page* 687)
Electric and Magnetic Research at Low Temperatures, 301, 338
Fluid Friction, 345
Fly-Wheels, Modern: by H. E. Campbell, 728 (*see also page* 718)
Foreign Office and Foreign Contracts, 559, *750*
Forrest (James) Lecture, *80*
"Fram," The, Electric Light on, 719
Frequency Teller, (*Campbell*) 437, (*Wulf*) 138
FRITH, J.:
Effect of Wave-Form on the Alternate-Current Arc, 11, 217
FRITH, J., and RODGERS:
The True Resistance of the Electric Arc, 93
Furnace, Electric (*Iron Smelting*) 687, (*Products*) 367, (*Volatilisation of Refractory Substances*) 688
Fuses, Aluminium Wires as, *33*

## G

Galvanometers, An Exhibition of, 168
Galvanometer Deflections, A Method of Reading, 786
Gas Company, A French, *versus* a French Municipality, 720
Gas Department, Management of Municipal Electrical Undertakings by, *197*
Gas *v.* Electricity Direct from Coal, *686*, 752
Gas Engines, (1,000 H.P.) 105, (*Belfast*) *103*, *467*, 476, 480, (*Producer Plant*) 109, (*Supply Stations*) *34*, 138
GIBBINGS, A. H.:
Extensions to Outlying Districts, 506
Guildford Street Mains, 349

## H

HANCHETT, G. T.:
Water Rheostats, 833
Heating, Electric, (*Hot Presses*) 385
HEAVISIDE, OLIVER:
Electromagnetic Theory, 139, 279, 369, 563, 558, 753
Dispersion, 470
HELMHOLTZ, H. VON:
The Electromagnetic Theory of Dispersion, 404. (*See also page* 470)
HESKETH, J.:
The Use and Economies of Rectifiers for Arc Lighting, 474
HESKETH, J., and RIDER, J. H.:
Combined Electric Lighting and Traction Plants, 409
HIBBERT, W.:
A One-Volt Standard Cell, 320
Honours for Scientific Men, *104*
Horseless Carriages, *34*, 52, 468, 499, (*Brochure*) 499, (*Circular Letter*) 562, (*The Engineer: Competition*) *230*
Hull Extensions, The, *498*

## I

**Incandescent Lamps—**
Business in the United States, 564
Carborundum for Filaments, 105
German Prices, 687
Hundred-volt One-candle Lamp, 398
Origin of the 110-volt Standard, 579
Reviving Burned-out Lamps, 773
Tests, Electric Glow Lamp [Preece] 733 (*See also page 780*)
220-volt Lamps in America, 451
"Indiana," Some Electrical Features of the United States Battleship, 803
Inductor Alternator Patent, The Mordey, 818
Inertia, Houston-Kennelly, Hypothesis of, *253*
Insulating Materials, Effect of Temperature on: by F. Sever, A. Morrell and C. L. Perry, 441 (*See also page 529*)
Insulating Materials, New (*Silex*) 612, (*Ambroin*) 817
Iron Smelting by Electricity, 687

## J

JACKSON, Prof. DUGALD C., and RICHTER, A. W.:
Tests of a Combined Electric Light and Electric Railway Central Station, 610
JAEGER, DR. W.:
The Standard Mercury Ohm of the Reichsanstalt, 569
Japan, Electrical Developments in, 592
JAUMANN, G.:
Electrostatic Deflection of Cathode Rays, 343
Jaumann's Theory of Longitudinal Vibrations, *531*
JECKELL, J. A.:
Cable Specifications and Tests, 376
Johannesburg as a Field of Employment for Electrical Engineers, *686*

## K

Kelvin Bridge, the Adjustment of: by R. Appleyard, 11
Kelvin Jubilee, *244*, 245, 366, 367, (*Programme*) 137, (*Lord Kelvin's Researches*) 233, (*Lord Kelvin and Submarine Telegraphy*) 236, (*The Electrical Measuring Instruments of Lord Kelvin*) 238, (*Group of Delegates*), 319
KELVIN (LORD):
Measurement of Electric Currents through Air at Different Densities, 763
KENNEDY, Prof. A. B. W.:
Physical Experiment in Relation to Engineering, 81

## L

Laboratories, Modern Scientific, The Evolution of: by Prof. W. H. Welch, 172
Lamps, Free, at Bradford, *815*
LAND, F. DE:
Recent Telephone Convention, 707
Telephone Situation, 834
LANGDON, W.:
On Railway Telegraphs, with Special Reference to Recent Improvements, 53, 86, (*Discussion*) 88
Laval Steam Turbine, Tests of, 697
Lavoisier, Statue to, 530
LEA, M. CAREY:
Rontgen Rays not present in Sunlight, 75
**LEGAL INTELLIGENCE—**
Bennett *v.* Druce, 323
Braulik *v.* Darton, 552
Callenders Co. *v.* National Telephone Co., 682
Chadwick *v.* British Insulated Wire Company, 26, 520
Clarke *v.* Julius Sax and Co., 26, (*Judgment*) 95
County of London and Brush Provincial Electric Lighting Company *v.* Vestry of St. Leonard, Shoreditch, 159
Cruto Incandescent Lamp Agency *v.* New and Mayne, 422
Electric Construction Corporation *v.* South Staffordshire Tramways Company, 24, 58, (*Judgment*) 220
Electric Construction Company *v.* Kurry and Young, 290
Elliott Bros. *v.* Sullivan, (*Judgment*) 256
Farringdon Works *v.* I.E.S. Accumulator, 551
**LEGAL INTELLIGENCE** (*Continued*)—
Franklin and Gould *v.* The Exeter Electric Lighting Company, 190
Frazer *v.* London and Provincial Supply Corporation, (*Judgment*) 221
Hopkinson Three-Wire Patent, 386
Jardine *v.* King, Mendham and Co. and Miles, 257, (*Judgment*) 290
Kensington Woodhouse Park Syndicate *v.* Central London Railway, 25
Lee and Hancock *v.* Piper, 387
Lightfoot *v.* Benzon and Smith, 422
London Electric Supply Corporation *v.* Prentice, 25
Medhurst *v.* Kyllin, 323, (*Judgment*) 355
National Telephone Co. *v.* Annand, 583
Rooper *v.* Holmes, 221
Rose *v.* Smith, 328
Von Buch *v.* Grant, 25
Westminster Electric Supply Corporation *v.* Young, 323
Willans' and Robinson Patent (*Application for Prolongation of*), 543
LEICK, W.
On the Magnetic Behaviour of Electrolytic Iron, Nickel, and Cobalt, 667
Li Hung Chang, 549
Light, On the Influence of, upon the Characters of the Influence Machine Discharge: by J. Elster and H. Geitel, 123
Lighthouses and Lightvessels, Electrical Communication with (*Fourth Report of Royal Commission*) *165*, 176, (*Fastnet*) 366
Lightning, Damage by, 200, 231, 265, 298, 399, 433, 591, (*Ashmolean Museum*) 332, (*Fatality at Liverpool*) 785
Loans, Municipal Electric Lighting, London County Council and, 434
Loans, Municipal Electric Lighting, Period of Repayment of, *229*
Localisation of Faults in Electric Light Mains: by F. C. Raphael, 8, 71, 170, 212, 314, 414, 484, 501, 593, 625, 721, 787
LODGE, PROF. OLIVER J.:
On the Seat of E.M.F. in a Cell, 755
Rontgen Ray Experiments, 169
Surviving Hypothesis concerning the X-Rays, 370
London, The Electric Supply Business in, 35
London Chambers of Commerce, Membership and Expenses, 221
Lorenz Apparatus, A New, 267
Losses of an Electric Supply System, 337
Low Temperature Research, *197*
Lubricants, The Testing of, 216
Lubricator, Boswell-Carter Self-Filtering, 216

## M

Magnesium, 167
**Magnetism—**
Amalgams, Magnetic Behaviour of, 720
Bismuth, 623, 687
Chattock Permeability Bridge, 94
Ewing Permeability Bridge, 41
Hysteresis at High Frequency [Klemencic] 333
Hysteresis in a Rotating Field [Beattie and Clinker], 723
Iron, Nickel and Cobalt, Electrolytic, Magnetic Behaviour of [Leick] *653*, 667
Liquids, 623
Magnetic Data and Testing of Iron and Steel, 115
Magnetic Observations, Comparison and Reduction of (*B. A. Report*), 823
Magnetic Research at Low Temperatures [Fleming] 301, 338
Magnetisation and Hysteresis of Certain Kinds of Iron and Steel [Du Bois-Taylor Jones], *90*, 595
Odessa Observatory, 443
Permeability Bridges (*Ayrton*) 566, (*Chattock*) 94, (*Ewing*) 41
Permeability and Hysteresis, Instrument for Testing, 568
Terrestrial (*Russian Anomalies*) 34, 687, (*Greenwich*) 199, (*Popular lecture: Dr. Fleming*) 688
Units at the Geneva Congress, 591
Mains, Guildford, 349
Manchester Electric Light Accounts, *297*
Manchester Ship Canal, Lighting of, 231
M'CARTHY, SAMUEL:
Steel Steam Pipes and Fittings, and Bernardos Arc-Welding in Connection therewith, 119
MCCOWEN, V. A. H.:
Electric Lighting in Belfast, 476
Melbourne Municipal Plant, *1*
Mercury Jets and Metals, Contact Difference of Potential of, *432*
Mercury Ohm, The Standard, of the Reichsanstalt: by Dr. W. Jaeger, 569. (*See also page 569*)
Meters, Prepayment, 785
Metric System, 418, 419, 489, *529*, 551, 583, 689
Mine Surveying Instruments, Action of Electric Currents on, 300
Mining, Electricity in, (*Baldwin Locomotive*) 561, (*Felten-Guilleaume Safety Cable*) 449, (*Portable Demonstration Plant*) 265, [Ravenshaw] 218, (*Youghiogheny River Coal Company*) 481
Montmorency Falls, Electric Plant at: by C. C. Chesney, 309
MORDEY, W. M.:
Load Losses in Dynamoes, 446
Motors (*Building Operations*) 561, [E. Wilson] *559*, 565, 613, (*Duquesne Steel Works*) 738, (Shipyards) 751, 818, (*Langdon-Davies*) 247, (*Method of Regulating*) 188, (*Navy*) 531, *559*, 576, 601, 803, 785, (*Polyphase*) 35, (*Machine-Tool Driving*) 488, (*Railway Efficiency*) *815*, 827, (*Shoe Factory*) 35, (Soignies Quarries), 433
Motors-Generators, A Winding for, 456
Municipal Control of Wiring and Fittings: by C. H. Wordingham, 282
Municipal Electrical Association, *166*, *197*, (*Manchester*) 231

Digitized by Google

## N

National Physical Laboratory, A, 687, *698*, 703
Navy, Electricity in, 231 (*Armour Plate Annealing*) 635, (*Beauchamp Tower Platform*) 137, ("*Indiana*") 803, (*Motors and Ventilation*) 531, [Eickenradt] *559*, 576, ("*Powerful*" and "*Terrible*" (785, (*Sellner Signalling System*) 332, (*The "Bowines"*) 601

## Letters to the Editor.

Accumulators, Positive Plates for ..... PERRY, JAMES, 710
Alternating Arcs and Wave-Forms ..... BEETON, S., TAYLOR, C. P., and BARR, J. M., 189; BLONDEL, A., 188; FRITH, J., 188; STEINMETZ, C. P. 126
Armature Losses ..... ESSON, W. B., 420; HAWKINS, C. C., 420; SAYERS, W. B., 420; SNELL, A. T., 420
An International (?) Congress ..... THOMPSON, S. P., 421
Atlantic Telegraph Cables ..... MOLL, O., 838
Combined Alternating and Continuous-Current Dynamo ..... RIDER, J. H., 613
Combined Electric Lighting and Traction Plant ..... RIDER, J. H., 677
Current Measurement by Means of Standard Resistances ..... FISHER, W., 58; WILSON, E., 58
Decimal Metric System, Nomenclature ..... "A MAN IN THE STREET," 551; CAMPBELL, ALBERT, 583
Direct Reading Wheatstone Bridge ..... HEAVISIDE, O., 459; EDGCUMBE, K., 773
Electric Mining Plant ..... HEATHER, H. J. S., 127
Electric Transmission at Romagnano ..... BROWN, BOVERI et CIE., 127
Electrical Trevelyan Rocker ..... APPLEYARD, R., 189; VAUGHTON, T. A., 222
Ewing Permeability Bridge, The ..... CHATTOCK, A. P., 94; CLULOW, P.D., 289
Freezing of Battery Cells ..... MAYCOCK, W. P., 741
Fundamental Magnetic Units ..... ALLEN, H. N., 126
Heating of Dynamos ..... WILSON, E., 222
Horseless Carriage Bill ..... WARD, RADCLIFFE, 127
Hysteresis of Iron in a Revolving Field ..... FLEMING, J. A., 189
Johnson and Phillips Arc Lamp ..... JOHNSON AND PHILLIPS, 490
Langdon-Davies Motor ..... LANGDON-DAVIES, W., 290
Lock Armoured Electric Light Cables ..... CALLENDER, T. O., 679; GLOVER AND SONS, W. T., 710
Long Distance Telephony ..... HEAVISIDE, O., 741
Low-Fall Water Power ..... PARDOE, G. T., 222
Melbourne Municipal Electric Light Station ..... ARNOT, A. J., 23
Negative Resistance of the Arc ..... AYRTON, W. E., 321; BLONDEL, A., 356; FITZGERALD, G. F., 386, 489; GRAY, A., 452; HEAVISIDE, O., 452; THOMPSON, S. P., 322, 421, 519
New Men and Old Plant ..... QUIN, R. C., 613, 742; COOPER, A. P., 677; PEARSON, J., 678
Non-Synchronous Two-Phase Alternate-Current Motor WILSON, ERNEST, 613
Photography of Lightning Flashes ..... LITTLE, W. G., 126
Photo-Printing of Tracings by Arc Light ..... "B. M. J.," 679; BLAKE, S. H., 710
Position of Science in Oxford ..... BURCH, G. J., 741
Power Factor ..... THOMPSON, S. P., 289; "THE WRITER OF THE ARTICLE," 289
Pringle and Kent's Surface Rail Electric Tramway .. SHARP AND KENT, 645
Protection Against High Voltage Shocks ..... BOZON, R., 421
Public Lighting by Arc Lamps ..... BLONDEL, A., 356; SHEPARDSON, G. D., 355
*Re*-Ozone. A Protest ..... ANDREOLI, E., 490
Rontgen Rays ..... BARR, J. M., 24; SWINTON, A. A. C., 221; THOMPSON, S. P., 290
Salary of Science Demonstrators ..... "WYBROW," 489
Seat of E.M.F. in a Cell ..... SWINBURNE, J., 807
Telegraphic Jubilee ..... WILKINS, J. W., 807
Temperature Attained in the Electric Furnace ..... HENWOOD, E. N., 583
Tests of Glow Lamps ..... BOTLEY, C. F., 773
Theory of the Secondary Battery ..... BUTLER, W. H., 126
Thompson's (Prof. S. P.) Suggestion ..... ANSELL, W. T., 807
Transparency of Filaments ..... ALLINGHAM, G. C., 95; CASSELLS, R. D., 189
"Universal" Engine, The ..... RAWORTH, J. S., 677

## TENDERS INVITED.

### VESTRY OF HAMMERSMITH.

ELECTRIC LIGHTING.

CABLES, ARC LAMPS AND POSTS, TRANSFORMERS.

The VESTRY of HAMMERSMITH are prepared to receive TENDERS for the following:—

(a) The SUPPLYING and LAYING of HIGH PRESSURE and LOW PRESSURE CABLES and PIPES.

(b) The SUPPLY and ERECTION of ARC LAMPS and LAMP POSTS.

(c) The SUPPLY and ERECTION of TRANSFORMERS and SUB-STATION EQUIPMENT.

(d) The SUPPLY and ERECTION of a 5 Ton OVERHEAD TRAVELLING CRANE.

Specifications, general conditions and form of tender can be obtained at the office of Mr. A. H. Preece, A.M.I.C.E., 39, Victoria-street, Westminster. Applications for any one or all of the above sections must be accompanied by a cheque for two guineas, which will be refunded on receipt of a bona fide tender.

Sealed tenders endorsed "Cables," "Arc Lamps," "Transformers," or "Crane," must be delivered at the Offices of the Vestry, 57, Fulham Palace-road, Hammersmith, not later than noon on WEDNESDAY, 27th May, 1896.

The Vestry does not bind itself to accept the lowest or any tender.

W. P. COCKBURN, Vestry Clerk.

Vestry Offices,
57, Fulham Palace-road, W.

### TOWNSHIP OF BRAY.

75-KW. STEAM ALTERNATOR, 200-H.P. LANCASHIRE BOILER, FUEL ECONOMISER, AND 100-H.P. ENGINE.

The TOWN COUNCIL, Bray (Ireland), will, at its meeting on the 18th May proximo, receive and consider TENDERS for:—

(a) One 75-k.w. STEAM ALTERNATOR.
(b) One 200-h.p. LANCASHIRE BOILER.
(c) One FUEL ECONOMISER, FEED PUMP, &c.
(d) One 100-h.p. VERTICAL HIGH-SPEED ENGINE.

To be delivered carriage free at the Bray Township Electricity Works.

Specifications, plans, and forms of Tender for either plant will be forwarded on application to undersigned. A deposit of £2. 2s., which will be refunded on receipt of bona fide Tender, must accompany each application.

Tenders, properly endorsed and sealed, will be received up to 10 a.m. on date mentioned.

The Council not bound to accept lowest or any Tender.

By order,

P. MACDONNELL, Town Clerk.

The Town Clerk's Office, Town Hall,
Bray, Ireland, April 28, 1896.

### THE METROPOLITAN ELECTRIC SUPPLY CO., LTD.,

offer the following

**WESTINGHOUSE ENGINES FOR SALE,**

owing to extensions and increase of H.P. required for larger Units.

All the Engines are in good condition and complete in all respects.

FIVE COMPOUND VERTICAL ENCLOSED ENGINES, each capable of indicating 320 H.P. when running at a speed of 250 revs. per minute, with a boiler pressure of 150 lbs. per square inch.

FIVE COMPOUND VERTICAL ENCLOSED ENGINES, each capable of indicating 250 H.P. when running at 280 revs. per minute, with a boiler pressure of 150 lbs. per square inch.

ONE COMPOUND VERTICAL ENCLOSED ENGINE capable of indicating 85 H.P. when running at a speed of 320 revs. per minute, with a boiler pressure of 150 lbs. per square inch.

The whole of the above Engines are fitted with variable expansion gear controlled by flywheel governors.

Permits to inspect may be obtained by application to the ENGINEER at 17, South-street, Manchester-square, W., who will give any further particulars.

### THE BRITISH ELECTRIC TRACTION (PIONEER) CO., LIMITED.

### PRESS OPINIONS.

**Electrician.**
**Lightning.**
**Electrical Review.**
**Insurance Observer.**
} *See previous Advertisements.*

**Electrical Engineer.**—"This Lamp is designed so as to preclude oxygen from reaching the arc. The carbons, therefore, are consumed very slowly, saving much time in trimming and carbon renewals. The Lamp, with two diffusing globes, gives a splendid light for interiors."

**Electricity.**—"The qualities which will tend to make it a success are: A very much lower cost of carbon renewals and labour, the possibility of using a low current, and the convenience of being able to connect the Lamp singly across circuits of 100 volts."

**Invention.**—"It has been proved that this Lamp gives out its light at nearly the maximum luminous intensity through a zone 90deg. in width, just about double the area equally illuminated by any of the short arc lamps generally in use."

**Irish News and Belfast Morning News.**—"The Lamp which has been fitted up outside 'The Ivesagh' seems to possess all the advantages claimed for the 'Jandus.' It gives a brilliant illumination without glare or flickering, and has a real artistic effect."

### TESTIMONIALS.

**Messrs. The DE LAVALS ELEKTRISKA BLOCK-BELYSNING, Stockholm** (The De Lavals House-to-House Electric Supply Company).—"The 35 Lamps you have sent us during the last six months have proved highly satisfactory in steadiness, economy and efficiency.

"We are so pleased with the lamp that we have decided to purchase the rights for the Scandinavian countries, and commence the manufacture of lamps there."—Signed for the Company by JOHN HAMMAR, M.I.E.E. (by power of attorney).

**Messrs. G. E. BELLIS & CO., Birmingham.**

"The Lamp we have is still working satisfactorily, and now burns about 195 hours."

**Messrs. A. WHITELAW & SON, Edinburgh.**

"We are highly pleased with the results given by the Jandus Lamp. It burns perfectly steady, and the trimming is simplicity itself."

**Messrs. BRISCOE & SHAW, Blackburn.**

"The Jandus Lamps supplied to us are burning with every success. Our clients at the paper mill are highly pleased with their Lamp, and inform us it is splendid for getting shades with. The Corporation Gas Committee are well pleased with the Lamp. Our client, Mr. Till, thanks us for advising him to use the Jandus Arc Lamp, so far being well satisfied."

**Messrs. JULES CHAGOT et CIE., Monceau-les-Mines.**

"Il résulte des essais que nous avons faits avec la première lampe Jandus que vous nous avez fournie, que la durée d'une paire de charbons, sur 4 amperes, est d'environ 220 heures."

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 937. [Vol. No. 1. XXXVII.] FRIDAY, MAY 1, 1896. PRICE SIXPENCE.

## NOTES.

THE patent No. 15,286 of 1885, granted to CARL AUER VON WELSBACH, of No. 63, Gumpendorfer Strasse, in the city of Vienna, Doctor of Philosophy, on the "MANUFACTURE OF AN ILLUMINANT APPLIANCE FOR GAS AND OTHER BURNERS," a patent the substantial validity of which was recently vindicated in the Queen's Bench Division, is one which has its interest for members of the electrical industry. The misfortunes of even our best friends are said to be a source of subtle satisfaction, and the spectacle of our good friends the gas engineers wasting their substance in patent litigation connected with an incandescent lamp, a method of spending money once so much affected by electrical engineers, is not without a peculiar relish of its own.

ANOTHER feature of interest in connection with this Welsbach case is that it affords a conspicuous instance of the comparative vulnerability of a patent, even when it is for an undoubted invention, and when it is drawn up with extreme care and skill. The ambit of the patent was purposely narrowed to an illuminating hood made of particular substances in a particular way, and the consequence is that the Sunlight Incandescent Gas Lamp Company, to use the words of Mr. Justice WILLS, "are taking a very valuable process bodily from WELSBACH without any remuneration."

THE Welsbach case, again, has afforded not only the daily papers, but a scientific contemporary, a text upon which to preach some extremely edifying sermons on the depravity of the expert witness. We ourselves have in our time said some hard things of the species, but we have never found it in our hearts to say anything quite so unkind as *The Times* has done. Doubtless anyone who takes to the calling of expert witness wears his reputation upon his sleeve for daws to peck at, and it must be admitted that in most instances the daws have good cause to peck; the clever fencing of an eminent witness anxious to be at once veracious, consistent and helpful to his clients, leaving upon the mind a decidedly painful impression of misplaced ingenuity. It is, however, the system rather than the individual who is to blame. Under the Patents, Designs and Trade Marks Act of 1883 either side can insist on the judge being assisted by an assessor. But, notwithstanding, this oft-recommended step is rarely taken by litigants. Why, we know not. Moreover, our pragmatic contemporaries could scarcely have chosen a worse example for the purpose of villifying the unfortunate expert witness than the one under consideration. Mr. Justice WILLS was most lavish with his encomiums. Of one witness (Mr. BALLANTYNE) he said:—"He is one of the most truthful and fairest-minded men I have seen in the witness box." Of another witness (Mr. SWINBURNE), the judge remarked that he answered a certain question "with that perfect frankness, truth and indifference to consequences which marked every answer that he gave, and made him the perfect idea of what a scientific witness should be." We feel sure that these certificates of virtue were thoroughly well deserved, and that Mr. Justice WILLS's ideal is the right one; but, alas, it is not the common one. Here we have Mr. G. F. EMERY in his recently published book on patent law, delivering himself of the following pleasantry:—" . . . . it is generally supposed that experts are not always strictly truthful; an ideal expert witness is a man who is unlikely to be entrapped by the wiles of the opposing counsel into admitting anything which will injure the side on which he is called." It is the too frequent realism of *this* ideal that brings the expert witness into such bad odour that hasty newspaper writers do not even think it necessary to glance at a patent case before they draw up an indictment against an entire species.

IN an article which we published on January 31st we criticised the design of the Melbourne municipal lighting station, in which, it will be remembered, a system of countershafting with ropes and belts is used to connect four engines to some 20 dynamos. A letter which we publish this week gives the reasons the Melbourne municipal electrical engineer, Mr. A. J. ARNOT, believes to have justified the particular design adopted. The letter is a curious commentary on the imperfect engineering facilities of the Victorian colony. It is surprising that at a hotel in Sydney in 1889 it was possible to use direct-coupled engines, while in Melbourne in 1891 the facilities for getting this type of plant were so completely absent that the best that could be done was to use countershafting. Nor is it any less surprising that a progressive colony should be blind to the mischievousness of the policy of imposing a 35 per cent. duty on machinery imported from the mother country, especially in regard to machinery which it is admitted the labour element in the colony is incapable of turning out. Such things are not to be defended, but they certainly support Mr. ARNOT's claim that the best that was possible in the circumstances was done.

Digitized by Google

Mr. Arnot, however, goes further than merely to advance this claim, and a considerable portion of his interesting communication is nothing else than a defence of the Melbourne system *per se*. No doubt, a coal consumption of "5·3lb. per unit generated" is a fair result for the Melbourne station; but when it is remembered that this is solely a public lighting station, and consequently works at steady full load, it is evidently unfair to compare this achievement with those of ordinary supply stations in this country. Mr. Arnot has cited Prof. Unwin as having said that "taking only the largest and best stations (in the United Kingdom) the consumption of coal varies in different cases from 7 to 12lb. per unit generated." That was for the year 1894. In that year, however, the coal bill of one of the London companies amounted to only 0·63d. per unit *delivered*; so that, assuming 20 per cent. of the units generated to have been used in the works and wasted in transmission, the cost per unit generated was only 0·5d. If this station had consumed so much as from 7lb. to 12lb. of coal per unit generated, the price paid for the coal could not have exceeded from 7s. 9d. to 13s. 4d. per ton, figures far below the price actually paid for good coal in London. Take another instance. At an important station in the South of England, where the plant is wholly direct-coupled, the average weight of coal per unit *sold* was well below 7lb., and the maximum at any time did not exceed 7·5lb., throughout 1895. The minimum weight was about 5·75lb. per unit sold. In this station the average consumption per unit generated could hardly have exceeded 5·8lb., and the minimum about 5lb., on the most liberal estimate. During the past twelve months many provincial stations have touched figures as low as 0·29d., 0·37d., 0·38d. and thereabouts per unit generated, and we very much doubt if any of these figures represent a consumption equivalent to 12lb. of good coal per unit generated. With unstinted admiration for the degree of success which the Melbourne station has attained under Mr. Arnot's management, we feel sure a still greater measure of success would have crowned his efforts had he been able to adopt arrangements more closely approximating to English practice of to-day.

In connection with the "Notes on Some American Alternating Current Machinery," which are commenced in our columns this week, we would call attention to one interesting development which has taken place in the United States. American engineers are now building alternators, the E.M.F. wave forms of which are specially adapted to the particular class of work intended to be done. Thus, low-frequency flat-topped and simple periodic waves are used for long-distance power transmission, while "saw-tooth" waves of higher frequency are more commonly used on distribution circuits. The General Electric Company of America seems to prefer the sine wave pure and simple for long-distance transmission, as this is said to give rise to less resonance than with any complex wave, whether flat-topped or peaked. We should have thought that in any but very long-distance transmission it would pay to make some concession to the transformers, and to use more peaky waves than the simple sine form. Curiously enough, too, the American experts—or, at any rate, some of them—seem to regard a flat-topped wave of *electromotive force* as being most efficient for supplying to transformers, whereas in this country it is the peaky wave of E.M.F., and the flat-topped wave of magnetising current that are considered best. The arguments put forward by the American experts in favour of their choice seem to us to confirm the correctness of English ideas.

The British Consul at New Orleans may or may not be an American, in any case he has been bitten with the transatlantic mania for figure juggling. Thus in his report to the Foreign Office he says: "A year or two ago the mule-car system was in force, by which much time was lost, as only five miles per hour could be made; now that the transit is by electric car a speed of 12 miles an hour is obtained. In New Orleans, with an average saving to each passenger of 12 minutes, there is an economy of 10,000,000 hours a year, equivalent to 1,250,000 days' labour of eight hours. If time is money, and one day's labour is worth 4s., which it certainly is at New Orleans, the electric cars are saving the city £250,000 a year in time." We should very much like to know on what grounds 12 minutes is taken to represent the time saved to each passenger by the new mode of traction. To assess the value of a day's labour in New Orleans at 4s. is also just a trifle sweeping and arbitrary. That is the beauty of this style of statistic spinning. Immense savings can be worked out on paper on the basis of tremendous assumptions that may or may not be warranted by the facts. However, so long as the sum saved sticks in the public mind whilst the chain of argument leading up to it is quickly forgotten, the arrow shot at a venture has hit its mark and, at any rate, one individual has done a good day's work. But electric traction no longer needs such adventitious aids; facts based on actual experience are now sufficiently numerous and sufficiently convincing, and flights into the realms of fancy are quite uncalled for.

We had thought the use of cast iron for live steam pipes was practically obsolete, and were surprised when we heard of the explosion, last January, of such a pipe at so modern a station as that at Dundee. The pipe in question, it appears from a recent Board of Trade inquiry, was a short bend forming part of a branch leading from the main steam range, and was so fixed that the expansion and contraction of the main could not but set up severe stresses in the bend. Moreover, the metal was of a spongy nature, through faulty casting. It is only to be wondered at that the pipe held out for three years. Engineers should remove any cast iron live steam pipes from their stations as speedily as possible; for if not, the pipes are practically certain to do as the Dundee one has done.

We commence this week the publication of a series of articles on a matter of considerable current interest, "The Localisation of Faults in Electric Light Mains." After discussing the various methods of testing the insulation resistance of high and low-pressure networks during working, the author will deal with the localisation of faults in electric

Digitized by Google

light systems, paying special attention to the ingenious automatic signalling and localising devices worked out by Herr KALLMANN of Berlin. Apart from possible future Board of Trade requirements in the matter of insulation tests and fault localisation, electrical engineers will not be living up to their reputation for scientific thoroughness unless they succeed in evolving reliable methods of automatically indicating and rapidly locating the leaks that occur on their mains. To this end Mr. RAPHAEL'S series of articles may prove helpful.

| **Cable Interruptions.** | Date of Interruption. |
|---|---|
| Puerto Plata—Martinique..... ..... | December 19, 1895. |
| Ceara—Maranham ..... | April 28, 1896. |

**Masonic Honours.**—We learn that the Grand Lodge of Freemasons has appointed Bro. T. A. Bullock, the popular London superintendent of the Eastern Telegraph Company, Past Grand Swordbearer.

**Pacific Cable Conference.**—A Reuter's telegram, dated Ottawa, April 27th, states that Sir Mackenzie Bowell and Sir Donald Smith will sail on May 9th for London as delegates to the Cable Conference. They will be accompanied by Mr. Sandford Fleming as expert adviser.

**Post Office Appointment.**—The Postmaster-General has made the following appointment: Mr. J. C Lamb, C.B., C.M.G., to be Third Secretary to the Post Office, in succession to Mr. Herbert Joyce, C.B., retired (Mr. Lamb will remain in charge of the Telegraph Branch).

**English as she is Spoke.**—While reading a translation from a German work describing a Continental electric supply station, we came across the following choice specimen of "English":—

"Everything which could have seduced the constructor to an experimental risk in order to supply with the demands of an extravagant electrical order, has been carefully avoided, and an engine was chosen whose working was, from a multitude of cases, known to be a satisfactory one."

**An Early Electrical Patent.**—On Sunday next, the 3rd inst., will terminate the 14 years' period which Patent No. 2,092, of 1882, granted to Charles Lever for his arc lamp, would have run had it not prematurely become void. The patent relates to "IMPROVEMENTS IN ELECTRIC LIGHT APPARATUS," and the claims are for a lamp in which the carbons are held apart when not in action, the feeding and regulation of the lamp being controlled by a shunt coil. The working of a number of such lamps in series is also claimed.

**Halifax-Bermuda Cable.**—According to the *Electrical Engineer* of New York it has been decided by the Bermuda Cable Company to keep secret the position of their cable from Halifax to Bermuda. According to the same authority Mr. D Budge, superintendent of the Halifax and Bermuda Cable Company, has gone to Ottawa to ask the Government for a subsidy to enable his company to extend its present cable from Bermuda to Jamaica.

**Berlin Industrial Exhibition.**—The supply of electrical energy at this exhibition will be in the hands of a syndicate, consisting of 12 of the leading German engineering firms. The total capacity of the generating plant will be over 4,600 H.P., made up of 22 units, ranging from 100 H.P. to 340 H.P. The current will be employed for lighting and power. There will be 500 arc lamps in the main hall, and 350 in the exhibition grounds. Electric energy will also be used for working a circular railway and some hundred electric motors. The generators will supply continuous and polyphase currents at low and high pressure.

**Cable Communication with the West Indies.**—In the House of Commons last week Mr. Chamberlain, in answer to Mr. Tomlinson, said he had received communications from the West India Colonies, representing the importance of establishing a through telegraphic communication between this country and those colonies, for the purpose of Imperial defence, as well as for commercial purposes. He had no reason to think that there were any insuperable constructive difficulties in effecting any such communication. Proposals on the subject were under consideration, and he hoped they would result in a cable being laid at no distant date.

**High Pressure Currents and Water Jets.**—An experiment to ascertain whether a high-pressure alternating current can be sent from a conductor to earth by means of a jet of water from the hose of a fire engine, and also whether the current can be transmitted to the firemen under such circumstance, was made a little time ago by Prof. Slaby, of Berlin. The overhead conductors of the Eichberg-Grünberg three-phase 10,000 volt transmission of power plant was used for the experiment. A voltmeter was connected between the metal mouthpiece of the water hose and the earth. On turning the water on to the three live conductors no flow of current to earth was noticeable.

**The P.Q. Atlantic Cable.**—We understand that the French cable steamer "François Arago," which has been engaged on the repair of this cable, has returned to France disabled, after experiencing very bad weather in the Atlantic. The Compagnie Française des Cables Télégraphiques has entrusted the repair of their Brest–Penzance and Penzance–St. Pierre sections to the Telegraph Construction and Maintenance Company, whose vessel, the "Seine," has just left England to undertake this work. As was mentioned recently in our columns the "François Arago" succeeded in recovering and buoying the St. Pierre end of the main cable in deep water. An engineer accompanies the "Seine" on behalf of the Compagnie Française.

**Applied Electro-Chemistry.**—Mr. Swinburne, in his first Cantor lecture on this subject at the Society of Arts on Monday evening, dealt merely with the elementary phenomena of electrolysis, though in a decidedly original manner. Grotthuss' hypothesis, Thomson's law, Helmholtz's law, Arrhenius' dissociation theory were discussed and caustically criticised, and a number of experiments were shown. In Lecture II. (May 4th) Mr. Swinburne will explain, "in a manner to be understanded of the people," the electrolytic production of caustic soda and bleach, and the electrolytic refining of copper. In Lecture III. he will deal with aluminium, sodium and "fused electrolysis," and in the concluding lecture, on May 18th, calcium carbide, aluminium and miscellaneous processes will be dealt with.

**The Government and the Telephone Trunk Wires.**—On the report this week of the financial resolution appropriating £300,000 for telegraph advances, Mr. Dalziel said that the House of Commons was entitled to a detailed statement as to the way in which the money was being spent. Mr. Hanbury said no portion of the money would go to the National Telephone Company, which had already received about £450,000 out of the £1,000,000 provided in the former Bill. The rest of that sum had gone to purchase wires for the trunk lines. The additional sum asked for was in order to complete the purchase of wires. Considerable discussion ensued, and an amendment was moved. Finally the amendment was withdrawn and the report agreed to. The Telegraphs (Advances) Bill was then brought in by Mr. Hanbury and read a first time.

**Iron and Steel Institute.**—In accordance with previous announcements, the autumn meeting of the Iron and Steel Institute will be held at Bilbao in September next. To convey the members to Bilbao, and to serve as a floating hotel, the ss. "Ormuz," 6,031 tons register, 8,500 H.P., one of the finest of the Australian liners belonging to the Orient Steam Navigation Company, has been detailed. The steamer will leave London (Tilbury) on August 29th, 1896. The routine of meals will be maintained in port, and communication with the shore will be provided without extra charge. The passage money is 20 guineas, which includes board on the steamer while in port, and is payable, one half on engaging passage and the balance three days before embarking, except as regards a few cabins. Passages may be engaged on and after May 7th, on application to the managers of the Orient Company, Messrs. Anderson, Anderson and Co., 5, Fenchurch-avenue, London, E.C.

**A Useful Engine Slide Rule.**—We have recently seen a useful and handy form of slide rule for the computation of

Digitized by Google

steam, gas and oil engine quantities. The slide rule is made of stiff cardboard, and measures about 6in. by 2½in. There are two sliders, placed side by side in the centre, and the working capacity of the instrument may be judged from the fact that the scales include indicated horse-power, brake horse-power, efficiency, firing or working strokes per minute, revolutions per minute, stroke, mean effective pressure, cylinder diameter, &c. All these quantities can be worked out without having to pull out and reverse the sliders, as in some other slide rules, which is a distinct advantage in respect of convenience, speed of working and durability. Among the useful things which can readily be accomplished with this slide rule are the following:—The computation of indicated horse-power from the quantities usually observed on an indicator trial, of brake horse-power from a brake trial, of the dimensions of an engine for any given indicated horse-power or brake horse-power and mean effective pressure, the mechanical efficiency, speed ratios of pulleys, velocities of belts or ropes, and the ubiquitous but useful "areas of circles." The range of use will be judged from the fact that the power scale is from 4 H.P. to 400 H.P., and may be indirectly reduced to 0·4 H.P. or raised to 4,000 H.P. The other scales are similarly of sufficient scope to cover a wide range of practice. We have carefully tested this slide rule with a number of examples, and find it accurate (to three figures with ease), expeditious and thoroughly practical over a wide range of engine quantities. We can confidently recommend it, and engineers will find it a great boon in undertaking tests, &c. Science teachers, too, would find it handy in checking class problems. Accompanying the slide rule is a card of instructions for use. This is the same shape and size as the slide rule, and both are contained in a stout case. The instrument is the invention of Mr. C. N. Pickworth, of Fallowfield, Manchester, from whom it may be obtained.

**Obituary.**—The death is announced of Mr. H. J. Vose, M.Inst.E.E., of Cardiff, Superintending Engineer of the Post Office Telegraphs for the South Wales District. Mr. Vose passed practically the whole of his official career in the engineering department of the telegraphs. He joined the staff of the late Mr. Edward Graves in 1871 Mr. Graves was then divisional engineer of the old north-western district, with headquarters at Birmingham. On Mr. Graves's promotion to the position of engineer-in-chief, in 1878, Mr. Vose followed him to London, and acted as his confidential assistant, with a short break, until Mr. Graves's death in November, 1892. Mr. Vose was then appointed, on the recommendation of the present engineer-in-chief, Mr. W. H. Preece, to the superintending engineership at Cardiff, in succession to Mr. J. Gavey, who removed to London on promotion as principal technical officer on the head office staff. Mr. Vose possessed in a marked degree the attributes that make a man a charming personal companion; but he was none the less an excellent man of business. He carried out the many delicate and important duties entrusted to him with admirable skill and tack; and he had the interests of the department he served very much at heart. He had been in failing health for a considerable time past, and for at least 12 months his condition had been such as to cause much anxiety to his friends and colleagues. But throughout the long course of the insidious disease from which he suffered, he never once lost heart. It was hoped that his comparative youth would eventually enable him to throw off the disorder, and recent reports of his condition favoured this view, but on Sunday last he suffered a severe relapse, and passed peacefully away on Tuesday morning. Mr. Vose was in his 46th year, and he leaves a widow and three children to mourn his loss. He will be greatly missed by his brother officers and by innumerable personal friends both within and without electrical circles. He was an enthusiastic Freemason.

**Recent Chemical Progress.**—In his second lecture on this subject at the Royal Institution Prof. Dewar commenced by describing the characteristic properties of acetylene, illustrating his remarks by experiments. This substance is one of those peculiar bodies, which, like arsenic, pass into the gaseous state at the ordinary atmospheric pressure without first liquefying. Acetylene is a most important body, as from it can be obtained ethylene, benzol, the cyanides, and in fact a whole range of organic bodies. Another product of the electric furnace whose application is daily extending, is aluminium. The Deville process gave us pure aluminium, but at a very high price, as it required the use of sodium, itself a costly metal. Then came the Cowles process which yielded it in greater quantities, but alloyed with other metals. To get it pure the metallurgist had to resort to the plan adopted by Sir Humphry Davy in the case of potassium and sodium, *i.e.*, separating the metal from one of its salts by electrolysis. As aluminium will not separate from oxygen except at a very high temperature, it is necessary to get a bath of some aluminium compound, such as cryolite, in a molten state. This is the process carried out at the works at Foyers, where the aluminium bath is kept molten in a large electric furnace, and the current at the same time separates the metal, which is tapped off at the bottom of the crucible. Now that aluminium can be cheaply produced, it is likely to be of great use, not only in the arts on account of its lightness and the beauty of its alloys, but also in metallurgical processes on account of its great reducing properties. Vautin has always employed it for purifying tungsten and other metals, examples of which were exhibited. Prof Dewar also showed the formation of an alloy of copper and aluminium. In this experiment he threw lumps of cold aluminium into a crucible of molten copper, the result being that the mass, instead of being cooled as one would have expected, was raised from the bright red heat of the molten copper to almost white heat, owing to the immense generation of heat produced by the union of the two metals to form the well-known alloy. At the temperature of the electric furnace silicon also forms a carbide, known commonly as carborundum, which is in the form of greenish crystals, and is coming largely into use as an abrasient.

**Contemporary Electrical Science.**—Mr. D. A. GOLDHAMMER, the distinguished Kasan physicist, throws in the weight of his opinion against the longitudinal vibration theory of the X-rays in a short Paper appearing in *Wiedemann's Annalen*. He pleads that all the peculiar properties of these rays are consistent with the assumption that they are very short ultra-violet waves. Such waves would be too small to be reflected by ordinary reflecting surfaces owing to roughnesses in polish. For the same reason they could not be polarised. But it would appear that this could be easily tested by trying reflection from *liquid* surfaces, which would need no polishing. Mr. Goldhammer gives no reason against the longitudinal character of these waves, but simply points out that in several theories of dispersion there is no deviation of infinitely small waves—which would account for the absence of refraction. The question of electrostatic discharge, so successfully tackled by Jaumann with the aid of the longitudinal theory, is left untouched by Goldhammer.—In the same number C. CHRISTIANSEN continues his disquisition on contact electricity. He has found that, among gases, oxygen and hydrochloric acid are about the only ones capable of producing a difference of potential between mercury and amalgams. But in any case, some gas is necessary.—FRANZ STREINTZ demolishes all experiments made to determine the polarisation of an electrolytic cell by the proof that the "resistance" of the cell is an indefinite function of the current intensity, and the polarisation, even if determinable, would be incapable of logical defination on the basis of present conceptions. The only solution is to abandon the idea of ohmic resistance as applied to a cell capable of polarisation.——An experimental proof of the truth of the theorem that an ellipsoid will be uniformly magnetised throughout in a uniform magnetic field has been attempted by O. GROTRIAN. He employed the ballistic method, using coils of different sizes to surround the ellipsoid in varying sections along the axis. But it was found impossible to make coils to fit ellipsoids, so he employed an iron sphere instead, which may be regarded as the limiting case of an ellipsoid. He then found that the theoretical conclusion was very closely verified. No influence of the direction of the "grain" of wrought iron could be discovered.——KARL L. SCHAEFER appears at last to have found a fairly strict means of measuring sound intensity. He uses a telephone adjusted to various sensibilities conveying a constant ticking sound from a clock which it is made just to "cover." He finds the law of inverse squares not to be strictly true.

# THE CROMPTON POTENTIOMETER: ITS USE AND CAPABILITIES.—VI.*

BY W. C. FISHER, ASSOC.MEM.INST.C.E.

*Resistance Standards.*

The system of measurement under description, in which the potentiometer itself forms but the main and most important item, would be very limited and curtailed in its usefulness and capabilities were it not for the necessary Standards of Resistance, inasmuch as current measurement and comparisons of E.M.F. of any reasonable range are impossible without them; it is, therefore, requisite thatsome description of their construction be given.

The demand for commercial standard resistances for the measurement of currents by means of the fall of potential over the same, more especially for large or heavy currents, is of comparatively recent growth, and might be said to be coincident with the growth of commercial electric lighting—that is to say, within the past six or eight years. Prior to that time there were naturally but few in use; and probably the first makers of such standards for heavy currents were Messrs. Crompton, for, having adopted the potentiometer system of measurement at their works, such standards were imperative to them as adjuncts that system. Some of these standards, relics of early days, are still in existence, and consist of one or many strips of thin platinoid sheet, sweated into heavy copper thimble connections, to which were attached both main and potential leads. They were satisfactory as things went in those days, but with increased accuracy and refinement in the main instrument an investigation into their behaviour revealed several defects in construction, as well as in the alloys used; these

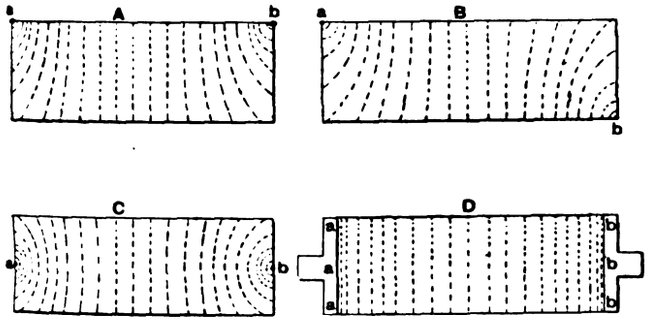

FIG 36.

have now respectively been remedied and abandoned. The two main points observed as defective were: First, the potential points were not sufficiently defined; and secondly, the alloys then in use were not sufficiently reliable. In the case of the first it was found impossible to obtain concordant and definite values unless the potential point was placed well within the area of the alloy itself, and *not* on the copper terminals.

During this investigation it was thought advisable to plot out on a given sheet of alloy the actual equipotential surface under given conditions. Some of the results or curves so obtained are shown in Fig. 36, in which the sheets A, B and C have the currents led in and out at the points *a* and *b*, with the result that the equipotential curves arrange themselves radially as shown, whilst in the case of D, having heavy copper connections extending the whole width of the sheet, they become parallel lines from end to end. These curves are only what one would expect, yet they serve to show strikingly that the shape of the main terminal and the position of the potential point are of considerable importance when great accuracy is desired; these curves were obtained and plotted upon actual sheets of alloy at the expenditure of much time and patience by Mr. A. C. Heap and some idea of the work involved may be obtained from the fact that the sheets measured approximately 20in. by 8in., and the curves were on an average about ½in. apart.

For a short time the potential terminals themselves were sweated on to the sheets, but as this was not deemed entirely satisfactory a change was sought in a small tapped hole and screw connection; but, as was pointed out by Prof. Viriamu Jones, the unscrewing of the screw and rescrewing of the same again in the plate was productive of an alteration in value; it afterwards proved, however, that without the necessity for unscrewing a change in value with time took place, which was due apparently to the formation of partial films of oxidation upon the surface or circumference of the screw. Prof. Jones also, at a British Association meeting, suggested the adoption of a peninsular-like projection, joined by a very narrow isthmus to the side of the sheet for the attachment of the potential terminal, as a method least likely to distort the equipotential surface, &c.; but this being somewhat impractical, the method shown at A B (Fig. 37) was adopted and is still in use; when this is suitably proportioned the cross-section of the sheet is but very slightly reduced, the equipotential surface is practically not disturbed, and by placing the V-cut at each end in the same direction a ready means of adjustment is obtained.

In the design and construction of such standards the first and chief point to be considered is their current capacity and consequent cross-section. In the early forms, as has already been stated, it was customary to construct them of very thin strips of alloy, having a considerable extent of radiating surface and leading naturally to economy in weight of material, but the extensive area exposed to atmospheric influence with its more or less chemical action upon the alloy employed, dependent upon the thickness of the strip, speedily alters its value by reducing the sectional area, &c. This, together with the fact that such standards being subject at times to rough usage, rendering mechanical strength a not unimportant consideration, has led to the adoption of considerably thicker sheets with consequent increased weight. So constructed these standards have a much longer life, and are in every way more reliable. Whilst using thin sheets recourse was had to gold plating as a protection from atmospheric influence, but in the case of large surfaces this led to considerable expense, and was abandoned in favour of japanning, enamelling, and flexible varnish.

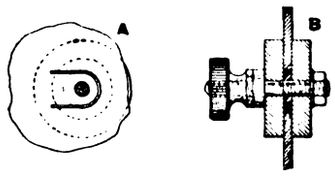

FIG. 37.

The current capacity and consequent size of such standards is, of course, variable from the ohm used for measuring currents up to one ampere, down to the lowest submultiples capable of carrying the largest currents; two samples of the latter were recently constructed for use at Kensington Court, being adopted by Mr. Miller for recording the total output of the station, having a maximum capacity of 6,000 amperes each.

No attempt is made here to describe pure laboratory standards with values that one is now fairly climatised to seeing defined by a stately row of ciphers carried on to attenuity, with perfect impunity, for the exact conditions under which they were obtained cannot possibly be repeated with any certainty, and proof of the inaccuracy of the last few figures accordingly need never be feared. Engineers do not ask for, do not want, and probably if they had, would doubt this degree of accuracy, and its uselessness as an unnecessary refinement to them is perfectly apparent when one considers the circumstances under which commercial standards are worked—amidst wide differences in temperature, mechanical upset, acid spray, and in some instances a chemical atmosphere, together with other causes that one does not usually obtain in a laboratory. One is not surprised therefore at the satisfaction expressed at a guaranteed accuracy within one-tenth per cent. in individual measurements of current or E.M.F., or even one-quarter per cent. in the measurement of power.

In a recently-published article upon foreign practice in the construction of standards the method of winding the standard coil high and then bringing it down to correct value by means of a fine wire shunt was described. This method was

* For previous articles see *The Electrician*, November 29th, December 6th, January 17th, January 31st, and March 13th. *Copyright.*

Digitized by Google

adopted in the calibration of potentiometer coils some years ago and abandoned, for the following reasons: the whole safety of the calibration of the coil was dependant upon the weak link of a fine wire, it was perfectly possible for this wire to be injured or severed without anything indicating the same, in fact as actually happened, it was possible for the coil to test up all right, and yet in the very act of removing it from the test table a disconnection of the fine wire to take place. The device is mechanically weak, therefore, in practice, it is far preferable to wind the coil—of substantial bare wire—slightly under value, and then by the mechanical process of removing metal by scraping or rubbing bring it up to its proper value. In this manner standards up to 10 ohms or more can be easily made and calibrated, and it is found more useful if necessary to wind between the convolutions of a standard coil, in place of the shunt described, a fine platinum wire to be used as a means of ascertaining the true temperature of the coil.

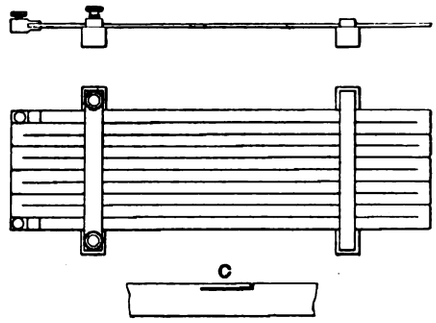

FIG. 38.

Fig. 38 is representative of the type of standard resistance used for the measurement of current up to 150 or 300 amperes. It consists of a sheet having alternate saw cuts from either end; the main terminals are fixed as shown, whilst the whole is braced with battens, the alloy being of sufficient thickness to stand knocking about. The potential is taken off a tongue, slit at the side of one of the limbs, as shown enlarged at C.

Fig. 39 is a type consisting of a single sheet (in some instances double), and is made to carry up to 1,500 amperes, the potential terminal in this case being fixed, as has already been described in Fig. 37, by being screwed into the tag shewn and secured by a lock nut, two ebonite washers ($a$, $b$) being interpolated.

Some remarkable inquiries with reference to standards might be here mentioned as being somewhat amusing. In one case a quotation was asked for a particular standard to be constructed

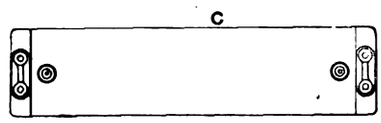

FIG. 39.

in solid alloy. The superficial area of this sheet when worked out, allowing it to be $\frac{1}{10}$in. in thickness, came to over 25 square yards; the dimensions when supplied proved sufficient. Another case which caused some surprise occurred with reference to a standard ohm, which was to be of somewhat large gauge platinum silver wire. Upon running out as a preliminary the probable cost, the wire alone came to between £70 and £80; this standard ohm was not made.

With reference to the question of alloys out of which such standards may be constructed, in the early days one had to be content with German silver or platinoid; but now, what with manganin, constantan, nickeline, rheotan, Krupp metal, and many others, one has infinite choice. In the case of German silver and platinoid, neither might be said to have been a success, the former becoming useless in a very short time, the latter becoming also, in course of time, very uncertain. Large currents appear to have a most demoralising effect upon both alloys, with the result that their values were never constant, varying in some cases day by day to a considerable extent, this being very marked if accidentally or unavoidably they were allowed to become very heated.

Constantan might be said to be fairly true to its name, and with it might be classed those members of the German silver family, nickeline and rheotane, whilst Krupp metal, with its abnormally high specific resistance of 86 microhms per cubic centimetre, and reputed virtue of remaining constant and unimpaired after being heated to 400°C., has the grave fault of quickly becoming oxidised and exceedingly "short" if subjected to atmospheric influences, more especially if there be a trace of acid vapour or spray present. Writing after an

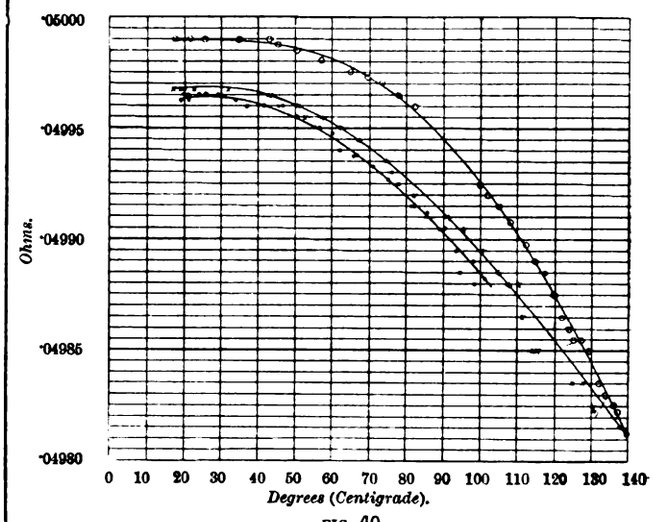

FIG. 40.

experience dating from its first introduction into this country, and after trial of all the known alloys, manganin is undoubtedly the best and most reliable of alloys that can be used for standards of the description in question, provided it is obtained in fit and proper condition. Complaints have from time to time appeared as to the difficulty in obtaining successive deliveries having identical electrical qualifications. When first placed upon the market such complaints were certainly just, for the specific resistances of successive batches varied by as much as several per cent.; but this difficulty seems to have been got over, and it is now possible to obtain specific

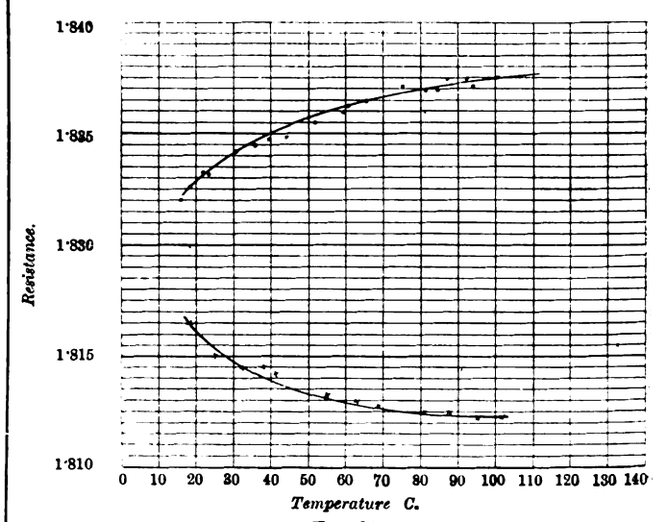

FIG. 41.

guarantees within reasonable limits. In any case, this complaint may to a certain extent be obviated by ordering large quantities at a time; but this is not always convenient. It is, however, certain that if this alloy be properly and consistently dealt with there is absolutely no difficulty in constructing reliable standards either of sheets in mass or of fine wires.

Fig. 40 gives the characteristic cycle of annealing and "ageing" curves common to the many tests made of sheet resistances, not one of which has been known to materially differ. At top we have the annealing curve when the resis-

Digitized by Google

tance is heated from normal temperature up to 140°C. Next the consequent natural cooling curve, whilst the lowest is a curve common to three or four "ageing" runs up to 100°C and down again. From this last curve it may be observed that the extreme

FIG. 42.

variation amounts to 0·15 per cent. approximately, or a mean over the whole of 0·00176 per cent. per degree, but in the early part of the curve the alteration is very slight, from 15deg. to 30deg. being practically unmeasurable and amounting, even when heated up to 50deg., to less than 0·0125 per cent. or 0·000356 per cent per degree.

This might very well be said to be all that is necessary in a commercial standard, and in a single alloy is not likely to be very much improved, but it is possible by the combination of two different alloys to construct a compound or compensating resistance standard having a temperature error which even between the extremes of normal and 100°C, may be neligible. The possibility of this is shown by Fig. 41, which gives the characteristic temperature curves of two alloys having respectively a negative and positive error, and from which it is seen that by combination in suitable proportions such a standard resistance as that described may be made, having a very small temperature error over a considerable range.

The demand for standards of high ohmic value, to carry a large and ever-increasing range of current, led to the adoption of such methods of construction as would not only decrease their weight but size also. Prof. Eric Gérard, at Liege, obtained this

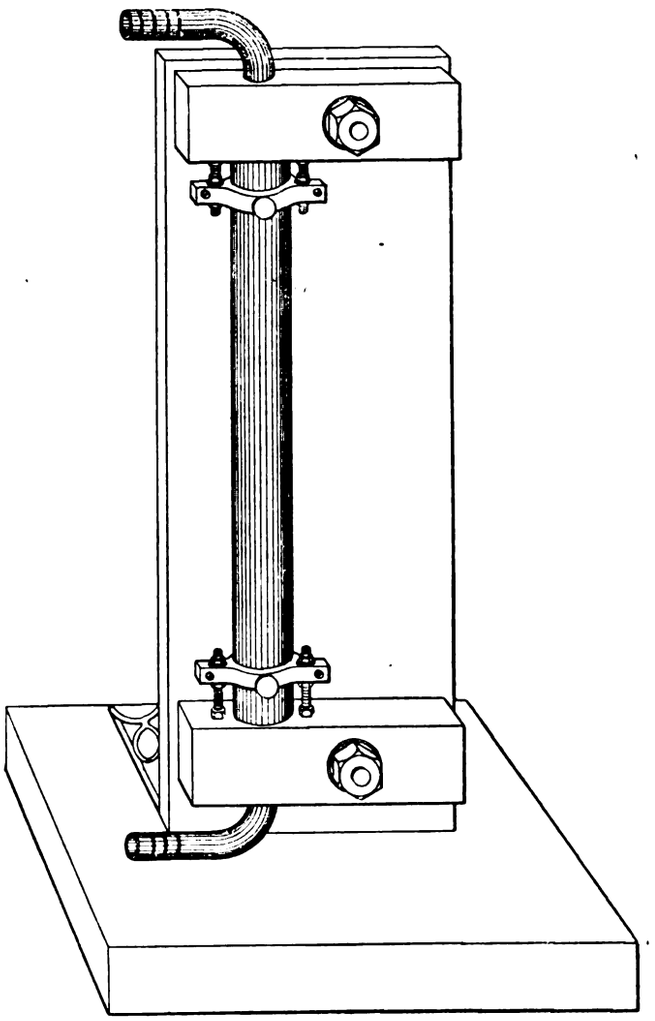

FIG. 43.—Perspective View of a Water Tube Resistance.

effect to a certain degree by plunging the standards in a tank of ever-flowing water. Several standards were made in this manner, but this method of construction was not deemed sufficiently practical or compact, added to which the amount of surface to be enamelled or protected from attack through electrolysis was still so great as to almost defy its being done efficiently, so that constant watching and overhauling was necessary. Experiments were then made to ascertain whether efficient and durable standards could not be made of tubular section, through which a constant stream of water could be maintained as a means of carrying off the heat generated by the current passing through the small section of conductor used. These proving satisfactory, this type of resistance was adopted, and is used wherever convenience or the exigencies of the case demand it. The tubes used are very thin, and are effectually protected inside by a thick coat of flexible enamel, and prove very efficient, even with a current density of something like 35,000 amperes to the square inch,

Digitized by Google

the flow of water required being no more than that obtained from the ordinary house service. At first thought it may be considered inadvisable to connect such a standard up to any earthed electric system on account of leakage and consequent electrolysis and shocks, but no danger need be anticipated provided an india-rubber connecting pipe of reasonable length be used, as from tests made it may be roughly taken that 30ft. of $\frac{3}{4}$in.-bore rubber hose pipe filled with water is equivalent in resistance to about 1 megohm. Such standards as are here described are represented by Figs. 42 and 43, the former being an ordinary standard placed in a bath of water, the latter one in which water is passed through the standard. It is somewhat curious to note that the latter cannot be worked in any other manner than vertical, as if the tube be placed inclined or horizontally air bubbles collect upon the sides, with consequent considerable local heating; it is also advisable, in order to prevent the standard accidentally acting as a fuse, to let the water enter from below and leave by the top orifice, also to run the water through in a preliminary manner the moment the standard is *in situ*, as then, even though the water may be cut off again, there will be a sufficient quantity within the tube to prevent accidental injury in the event of the current being turned on unexpectedly.

## THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS.*

BY F. C. RAPHAEL.

### Insulation Testing of Low-Pressure Networks During Working.

*Permanently Earthed Networks.*

When one main of a network is permanently earthed throughout its length, it is impossible to test the fault resistance of the other main or mains during working. Such networks should preferably be provided with "fault-signalling networks,"† to be described later. Otherwise, it is only possible to discover the existence of faults through abnormal increases of current, drops of voltage, blown fuses, &c.

At some central stations one of the mains is permanently earthed at the station end through an ammeter, being insulated at every other point. On a fault suddenly occurring in any part of the network, there will be a sudden variation in the current flowing through this testing ammeter. But, except in the case of a fault thus suddenly appearing, the reading of the ammeter is not a sufficient indication of the state of the insulation of the network, although it is usually considered so. Suppose, for instance, that the ammeter earthing the middle wire of a three-wire network shows a current flowing towards earth, and that during a certain week this reading gradually decreases. The cause of this may be a decrease in the leakage from the negative main, or else the development of a fault on the positive main or of a bad fault on the middle wire, so that the engineer-in-charge would not be justified in assuming that something was wrong. A fault occurring on the middle wire must be very bad to occasion an appreciable alteration in the deflection of the ammeter. Moreover, if the fault resistances of the positive and negative mains were equal in a three-wire network (or if the equation $\frac{2}{f_1}+\frac{1}{f_2}=\frac{1}{f_4}+\frac{2}{f_5}$ were satisfied in a five-wire network), no current would pass through the ammeter, however good or bad the condition of the middle wire might be.

The current in amperes flowing from the middle wire to earth through the testing ammeter is, in fact, given by the formula

$$C=\frac{\frac{1}{f_d}-\frac{1}{f_b}}{\frac{1}{F}+\frac{1}{g}}\cdot\frac{V}{g} \text{ for a three-wire network, . . . (1)}$$

$$\text{or } C=\frac{\left(\frac{2}{f_e}+\frac{1}{f_d}\right)-\left(\frac{1}{f_b}+\frac{2}{f_a}\right)}{\frac{1}{F}+\frac{1}{g}}\cdot\frac{V}{g} \text{ for a five-wire network, . . . . (2)}$$

F being the fault resistance of the whole network in ohms;

$f_a$, $f_b$, $f_c$, $f_d$ and $f_e$ being the fault resistances of the several mains respectively from + to −;

$\left(\frac{1}{F}\right.$ is, therefore, $\frac{1}{f_a}+\frac{1}{f_b}+\frac{1}{f_c}+\frac{1}{f_d}+\frac{1}{f_e}$ in a five-wire network, or $\left.\frac{1}{f_b}+\frac{1}{f_c}+\frac{1}{f_d}\text{ in a three-wire network}\right)$;

V the difference of potential in volts between any two adjacent mains (between $a$ and $b$ or $b$ and $c$, &c.), and

$g$ the resistance of the ammeter in ohms.

In a two-wire network whose negative wire is earthed through an ammeter

$$C=-\frac{\frac{1}{f_b}}{\frac{1}{F}+\frac{1}{g}}\cdot\frac{V}{g}=-\frac{\frac{1}{f_b}}{\frac{1}{f_b}+\frac{1}{f_c}+\frac{1}{g}}\cdot\frac{V}{g}, \quad . \quad . \quad . \quad (3)$$

where $f_b$ and $f_c$ are the fault resistances of the positive and negative mains respectively.

This ammeter can thus only partially be depended upon as an indicator of faults, but as such it is better than none at all. The instrument should be of a type whose pointer deflects to different sides of the zero for currents of different directions, or it should be provided with a second needle to indicate the direction of the current. If a current flowing through it *from* the middle wire *to* earth be considered to give a + deflection, then a + deflection indicates that the positive side of the network is the better insulated, and a − deflection indicates that the negative side is the better insulated.

There is still another kind of permanently-earthed network—viz., that whose middle wire is earthed at the feeding points only. These networks—as, in fact, any which are permanently earthed—should in preference have "fault-signalling networks," as described later; but if these latter have not been provided, it is also possible to use the earthed-ammeter method of testing just described. At one feeding point, which is conveniently accessible, an ammeter of a fraction of an ohm resistance is permanently connected between the middle wire and earth. At the other feeding points the middle wire is not directly earthed, but is earthed in each case through a resistance coil of the same resistance as the ammeter. These resistances being so low, the advantages of earthing at the feeding points are still secured. The ammeter should be read each day, and the same inferences drawn from its readings as in the previous case considered.

The equations connecting the current through the ammeter with the fault resistance of the network will now be

$$C=\frac{\frac{1}{f_d}-\frac{1}{f_b}}{\frac{1}{F}+\frac{n}{g}}\cdot\frac{V}{g} \text{ for a three-wire network, . . . (4)}$$

$$\text{and } C=\frac{\left(\frac{2}{f_e}+\frac{1}{f_d}\right)-\left(\frac{1}{f_b}+\frac{2}{f_a}\right)}{\frac{1}{F}+\frac{n}{g}}\cdot\frac{V}{g} \text{ for a five-wire network, . . (5)}$$

where $n$ is the number of earthed feeding points.

For a two-wire system whose negative wire is earthed at the feeding points as above described,

$$C=-\frac{\frac{1}{f_b}}{\frac{1}{F}+\frac{n}{g}}\cdot\frac{V}{g} \text{ or } -\frac{\frac{1}{f_b}}{\frac{1}{f_b}+\frac{1}{f_c}+\frac{n}{g}}\cdot\frac{V}{g}; \quad . \quad . \quad . \quad (6)$$

$f_b$ and $f_c$ are in this equation the fault resistances of the positive and negative mains respectively.

*Networks which are not Permanently Earthed.*

The insulation resistance of a network should be tested frequently—say once a day—by one of the four following

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

methods, and a record of the readings should be kept. A variation in the readings indicates a change in the insulation resistance of the mains.

*Method 1.**—An ammeter or voltmeter, which gives readings on both sides of zero, has one terminal connected to earth, and the other terminal is connected in turn to each main.

If $d_1$ and $d_2$ be the readings obtained from two adjacent mains (*i.e.*, for instance, between the middle wire and one of the outer wires in the case of a three-wire network); if V be the working pressure between these two mains, in volts, and $g$ the resistance of the testing ammeter or voltmeter, in ohms, the insulation resistance of the whole network in ohms is given by the simple formula

$$F = \frac{V}{d_1 - d_2} - g, \text{ if an ammeter be used for the test,} \quad . \quad (7)$$

$$\text{and } F = g\left(\frac{V}{d_1 - d_2} - 1\right), \text{ if a voltmeter be used.} \quad . \quad . \quad . \quad (8)$$

In a two-wire network the fault resistance of *each* main may also be calculated from these readings:—

If an ammeter be used—

$$\left.\begin{aligned} f_1 &= \frac{V - g(d_1 - d_2)}{-d_2} \\ \text{and} \quad f_2 &= \frac{V - g(d_1 - d_2)}{d_1} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (9)$$

If a voltmeter be used—

$$\left.\begin{aligned} f_1 &= \frac{g\{V - (d_1 - d_2)\}}{-d_2} \\ \text{and} \quad f_2 &= \frac{g\{V - (d_1 - d_2)\}}{d_1} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (10)$$

The expression $(d_1 - d_2)$ in all the above formulæ is the algebraical difference between the two readings—that is to say, if the deflections are to opposite sides of the scale, they must be added.

It is not absolutely necessary to use instruments which give deflections on both sides of the scale, though it is more convenient. For example, if $d_1$, $d_2$ and $d_3$ are the readings obtained from the mains of a three-wire network,

$$d_1 - d_2 = d_2 - d_3.$$

And in a five-wire network

$$d_1 - d_2 = d_2 - d_3 = d_3 - d_4 = d_4 - d_5.$$

It is thus easy to see what sign to give to the reading.

In a two-wire network the two readings are always on opposite sides of zero, and they must therefore be added.

Also, in a two-wire network the readings $d_1$ and $d_2$ are proportional to the relative insulation resistances of the two mains, so that, on a fault occurring, it is at once apparent in which main it is. In a three or five-wire system, if one of the outer mains has developed a fault, there will be a considerable change in the reading from the middle main. In the case of a fault of the same resistance on the middle wire, the reading from the middle wire itself will not alter so much, the change in the readings from the other mains causing the increase in the value of $(d_1 - d_2)$. This can be seen by studying the examples which follow.

The instrument to choose for the test should have as low a resistance as practicable, but this must be made to depend to a certain extent on the normal insulation resistance of the network. In a large network, whose normal resistance is only a few ohms, an ammeter of very low resistance would take too much current, whereas a voltmeter would have too high a resistance. In such a case a good plan is to first decide the maximum testing current to be allowed, and then to procure an ammeter reading to this current, and to use a resistance in series with it if necessary. The coils of an ordinary Wheatstone's bridge resistance box are not suitable for this, as they would be heated by the current. Coils of bare copper or iron wire do very well for the purpose; the size of the wire must be so large that it does not get heated. The value of $g$ is then the resistance of the instrument *plus* the resistance of the coil.

* This method was first described by Gustav Frisch, of Vienna. *Zeitschrift für Elektrotechnik*, May 1, 1889.

If the approximate fault resistances of the mains be known, a value of $g$ can be chosen so as to give suitable values to $d_1$, $d_2$ and $d_3$ in the following equations:—

$$\left.\begin{aligned} d_1 &= \frac{V}{g}\left(\frac{\frac{1}{f_3} - \frac{1}{f_1} - \frac{1}{g}}{\frac{1}{F} + \frac{1}{g}} + 1\right) = \frac{V}{g}\left(\frac{\frac{1}{f_2} + \frac{2}{f_3}}{\frac{1}{F} + \frac{1}{g}}\right) \\ d_2 &= \frac{V}{g}\left(\frac{\frac{1}{f_3} - \frac{1}{f_1}}{\frac{1}{F} + \frac{1}{g}}\right) \\ d_3 &= \frac{V}{g}\left(\frac{\frac{1}{f_3} - \frac{1}{f_1} + \frac{1}{g}}{\frac{1}{F} + \frac{1}{g}} - 1\right) = -\frac{V}{g}\left(\frac{\frac{1}{f_2} + \frac{2}{f_1}}{\frac{1}{F} + \frac{1}{g}}\right) \end{aligned}\right\}, \quad (11)$$

where $f_1$, $f_2$ and $f_3$ are the fault resistances of the positive, neutral and negative mains respectively, and F is the insulation resistance of the whole network, $\frac{1}{F}$ being $= \frac{1}{f_1} + \frac{1}{f_2} + \frac{1}{f_3}$.

For a five-wire system the equations are:—

$$\left.\begin{aligned} d_1 &= \frac{V}{g}\left(\frac{h - \frac{2}{g}}{\frac{1}{F} + \frac{1}{g}} + 2\right) \\ d_2 &= \frac{V}{g}\left(\frac{h - \frac{1}{g}}{\frac{1}{F} + \frac{1}{g}} + 1\right) \\ d_3 &= \frac{V}{g}\left(\frac{h}{\frac{1}{F} + \frac{1}{g}}\right) \\ d_4 &= \frac{V}{g}\left(\frac{h + \frac{1}{g}}{\frac{1}{F} + \frac{1}{g}} - 1\right) \\ d_5 &= \frac{V}{g}\left(\frac{h + \frac{2}{g}}{\frac{1}{F} + \frac{1}{g}} - 2\right) \end{aligned}\right\}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$

$h$ being $\frac{2}{f_5} - \frac{2}{f_1} + \frac{1}{f_4} - \frac{1}{f_2}$,

and $f_1$, $f_2$, $f_3$, $f_4$, $f_5$ being the fault-resistances of the several mains, in order from the outer positive to the outer negative.

For a two-wire network:—

$$\left.\begin{aligned} d_1 &= \frac{V}{g}\,\frac{\frac{1}{f_2}}{\frac{1}{f_1} + \frac{1}{f_2} + \frac{1}{g}} \\ d_2 &= -\frac{V}{g}\,\frac{\frac{1}{f_1}}{\frac{1}{f_1} + \frac{1}{f_2} + \frac{1}{g}} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$

For networks of somewhat higher insulation—perhaps from 40 or 50 ohms upwards—large currents can no longer be obtained between the mains and earth; then there is no necessity to put a resistance in series with the ammeter, though a resistance of a few ohms may be put in series with it as a safeguard. For still higher insulation resistances the testing currents get smaller, and either milliampere-meters or *low*-resistance voltmeters should be employed. The latter are not at present obtainable from instrument makers, as, for usual central-station practice the higher the resistance of the switchboard voltmeter the better. There is, however, no reason

Digitized by Google

why special instruments should not be made, wound with low-resistance coils for this purpose. A hot-wire voltmeter (such as the Cardew) having a lower resistance, will serve to give indications of faults, but it will not give an accurate measurement of the insulation resistance, as its resistance is not constant, but depends on the reading. An ordinary voltmeter, which has, as a rule, a resistance of about 1,000 ohms, should only be used for testing networks whose insulation resistances are at least over 100 ohms. When used for lower insulation resistances, changes in the fault-resistance of the middle wire produce but small changes in the voltmeter readings (*see* Example 4). Moreover, a small error in reading the instrument will cause a large error in the calculated value of the insulation resistances. For instance, on a network of 50 ohms insulation resistance, in which V is 100 volts, an error of half a volt in the reading $d_1 - d_2$ produces an error of about 10 per cent.

For small networks whose insulation resistances are 1,000 ohms or more, an ordinary electromagnetic voltmeter will give very good results, or a high-resistance galvanometer may be employed. As this latter would not read directly in volts, it must first be connected across the mains to give V in terms of the galvanometer scale readings, and then the readings $d_1$, $d_2$ and $d_3$ should be taken between each omnibus bar and earth. The insulation resistance will be then, as before,

$$F = g\left(\frac{V}{d_1 - d_2} - 1\right),$$

V, $d_1$ and $d_2$ being the galvanometer readings and not necessarily volts. An extra refinement would be to use a galvanometer with a shunt box with compensating resistances (*see* "Kempe's Handbook of Electrical Testing," p. 84). But it has already been shown above, and it is also apparent from the examples which follow, that measurements of sufficient accuracy can be made with ordinary and less expensive instruments.

The ideal way to use Method 1 is to have a recording voltmeter connected between one of the outer mains and earth (or between each of the outer mains and earth), and to test once daily with an ammeter or voltmeter, as above described. Then, if only a slight variation in the insulation resistance—and consequently in readings of the testing ammeter or voltmeter—has occurred, it can at once be seen, by examining the recording voltmeter curve, whether this has been due to a sudden alteration in the conditions—*i.e.*, by the development of a fault—or by a gradual decrease in the insulation resistance. If the resistance of the recording voltmeter is high compared with the insulation resistance of the network, it is not necessary to disconnect it for the ammeter test.

In every case in which an instrument (whether a recording voltmeter or an ordinary voltmeter or ammeter) is connected between a main and earth, a fuse should be inserted between the instrument and the main, not between the instrument and the earth.

Instead of one voltmeter or ammeter having a wide range, two instruments may be used, having "open" scales at the parts where the readings occur. If this is done their resistances must be equal, or, if of different resistances, the lower resistance instrument must have a resistance coil in series with it to make up the difference.

A method of testing which is used very frequently in a three-wire network is to connect a high-resistance voltmeter between each of the two outer mains and earth. Then, if the readings are slightly different, the mains are pronounced to be in good condition. If one reading is considerably lower than the other, the outer main on that side is considered the culprit; and if the two readings are equal, the middle main is presumed to be faulty. The error and insufficiency of this method is evident from the foregoing and from the examples below. If the reading is 0 when the instrument is connected to the middle wire, it simply means, in a three-wire network, that the fault resistances of the positive and negative mains are equal; in a five-wire network, that

$$\frac{2}{f_1} + \frac{1}{f_2} = \frac{1}{f_4} + \frac{2}{f_5} \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

**Example I.**—*This shows Stages in the Development of a Fault in the Middle Wire of a Three-wire Network.*

V = 105 volts. $g$ = 1 ohm.

| *a.* (Normal Readings.) | *b.* | *c.* | *d.* |
|---|---|---|---|
| | Amp. | Amp. | Amp. |
| From positive main, $d_1$ = | +4·0 | +4·5 | +7·3 | $d_1$ off scale + |
| From middle main, $d_2$ = | +0·25 | +0·25 | +0·25 | $d_2$ +0·15 amp. |
| From negative main, $d_3$ = | −3·5 | −4·0 | −6·9 | $d_3$ off scale − |
| $F = \frac{V}{d_1 - d_2} - g$ (or $\frac{V}{d_2 - d_3} - g$) | | | | |
| $= \frac{105}{3·75} - 1 = 27$ ohms. | | F = 24 ohms. | F = 13·8 ohms. | F about 2 ohms. |

**Example II.**—*Example of the Development of a Fault in the Positive Wire of the Same Network.*

V = 105 volts. $g$ = 1 ohm.

| *a.* (Normal Readings.) | *b.* | *c.* |
|---|---|---|
| From positive main, $d_1$ = | +4·0 amp. | +3·8 amp. | +2·7 |
| From middle main, $d_2$ = | +0·25 amp. | −3·7 amp. | $d_2$ off scale − |
| From negative main, $d_3$ = | −3·5 amp. | −11·1 amp. | $d_3$ off scale − |
| F = 27 ohms. | | F = 13 ohms. | F about 2 ohms. |

**Example III.**—*An Incipient Fault in the Negative Wire of the Same Network.*

V = 105 volts. $g$ = 1 ohm.

| *a.* (Normal readings.) | *b.* |
|---|---|
| From positive main, $d_1$ = +4·0 amp. | $d_1$ = +4·6 amp. |
| From middle main, $d_2$ = +0·25 amp. | $d_2$ = +0·6 amp. |
| From negative main, $d_3$ = −3·5 amp. | $d_3$ = −3·5 amp. |
| F = 27 ohms. | F = 25 ohms. |

*Use of Voltmeter of 1,000 ohms Resistance.*

The following two examples are purposely extreme cases to show how unsuitable a voltmeter is for the test when the insulation resistance of the network is low.

**Example IV.**—*Incipient Fault in Middle Wire.*

V = 110 volts. $g$ = 1,000 ohms.

| *a.* (Normal readings.) | *b.* |
|---|---|
| From positive main, $d_1$ = +111·3 volts | $d_1$ = +111·1 volts |
| From middle main, $d_2$ = + 6·7 volts | $d_2$ = + 5·7 volts |
| From negative main, $d_3$ = − 98·0 volts | $d_3$ = − 99·8 volts |
| $F = g\left(\frac{V}{d_1 - d_2} - 1\right)$ or $g\left(\frac{V}{d_2 - d_3} - 1\right)$ | |
| $= 1{,}000\left(\frac{110}{101·6} - 1\right) = \frac{1{,}000 \times 5·4}{101·6}$ | F = 43 ohms. |
| = 52 ohms. | |

**Example V.**—*Incipient Fault in the Negative Main of the Same Network.*

V = 110 volts. $g$ = 1,000 ohms.

| *a.* (Normal readings.) | *b.* |
|---|---|
| From positive main $d_1$ = +111·3 volts | $d_1$ = +128 volts |
| From middle main $d_2$ = + 6·7 volts | $d_2$ = + 23 volts |
| From negative main $d_3$ = − 98·0 volts | $d_3$ = − 83 volts |
| | (Taking the mean between $d_1 - d_2$ and $d_2 - d_3$) |
| F = 52 ohms. | $F = 1{,}000\left(\frac{110}{105·5} - 1\right)$ |
| | $= \frac{1{,}000 \times 4·5}{105·5} = 43$ ohms. |

(*To be continued.*)

## PHYSICAL SOCIETY.

At an ordinary meeting of the Physical Society, held on April 24, 1896, Capt. W. de W. Abney, president, in the chair, a Paper by Mr. R. A. LEHFIELD on

**"Symbolism in Thermodynamics,"**

was, in the absence of the author, read by the Secretary.

The author proposes a system of about 24 separate symbols for the different quantities in thermodynamics.

Prof. SILVANUS THOMPSON said he was not at all favourably impressed with the symbols proposed. In particular it was becoming usual to restrict the use of Greek letters to the representation of specific quantities or angles, and the author's proposal seemed, in this way, a retrograde step.

Prof. PERRY said he did not care for the suggested symbols.

Mr. ELDER thought the author's system would be a very severe tax on the memory, for he did not make use of suffixes, as was ordinarily done, which in a great measure define the symbol to which they are attached.

Mr. APPLEYARD read a Paper on

**"The Adjustment of the Kelvin Bridge."**

In a recent Paper read before the Society Mr. Reeves had described a modified form of Kelvin bridge, in which a double adjustment was necessary. The author proposes to employ two wires, stretched side by side, with a sliding contact in connection with the galvanometer on each. These contacts are rigidly connected together so that the segments into which one wire is divided necessarily bear to one another the same ratio as do the segments of the other wire. Hence a single adjustment is sufficient to give balance.

Mr. REEVES said that apparently the author had completely missed the object of his (the speaker's) Paper. For the object there aimed at was to make use of such sets of resistance coils as are always to be found in any laboratory. In the author's arrangement it would be necessary to carefully calibrate the two wires, and also, since the resistances used must necessarily be small, to determine the resistance of the contacts.

Prof. AYRTON (communicated) said the author's suggestion was ingenious, but did not obviate the necessity for much of Mr. Reeves' "addition." Further, Mr. Reeves' proposal to employ ordinary resistance boxes was not made because such resistances are absolutely necessary, but because, since they are to be found in any electrical laboratory, their use saves the expense of such a wire resistance accurately calibrated as Mr. Appleyard employed.

Mr. APPLEYARD, in his reply, said that his instrument was designed for use in a factory where the time saved in making a series of tests was of more importance than the cost of the instrument.

Mr. J. FRITH read a Paper on

**"The Effect of Wave-Form on the Alternate-Current Arc."**

The author finds that an arc has the power of modifying the wave-form in a circuit in which it is included. Thus, in the case of a dynamo for which on open circuit the curve of E.M.F. was decidedly peaked, it was found that when this dynamo was employed to feed an arc that the curve became changed to a flat-topped form. It is interesting to remember that the candle-power of the arc is greater when the wave-form is flat-topped than when it is peaked. By altering the resistance in series with the arc it is possible to alter the character of the curve, for as the resistance in series with the arc increases the arc affects the wave-form less and less. In some recent experiments described by Dr. Fleming a resistance of about 7 ohms was used in series with the arc, so that the wave-form of the generator, which is not an efficient form, was forced on the arc. In practice, however, where a resistance is not used in series with the arc, this is not the case, and the differences between the efficiency obtained for alternate-current arcs in the laboratory and that claimed in practice may thus be accounted for.

Mr. BLAKESLEY said it seemed as if the more nearly the alternate current resembles a direct current—*i.e.*, the longer in each period the the current remains constant—the greater is the efficiency of the arc.

Mr. PRICE asked what was the cause of the reaction of the arc on the wave form.

Prof. AYRTON (communicated) considered the author's suggestion of great importance as bearing on the question of the efficiency of the alternate-current arc.

Prof. S. P. THOMPSON said that the dynamo employed by the author was one in which there was a large quantity of iron in the armature, so that the self-induction was large. Was it not on account of this large coefficient of self-induction, which would tend to keep the current constant, that the arc was able to alter the wave curve? If an arc is connected to the mains of a supply station in which a number of machines in parallel are feeding a number of lamps, would the arc still be able to affect the wave form of the current?

Mr. TREMLETT CARTER asked if the author had tried the effect of replacing the arc by a resistance such that it would absorb the same volts as did the arc, and comparing the curves for the current and impressed potential difference with those obtained with the arc.

The AUTHOR, in his reply, said that the effect of the self-induction of the machine was shown in the curves. Current curves had not been taken with the arc straight on the machine. The current and self-induction were the same for all the curves, the voltage of the machine being increased by increasing the field when resistance was placed in series with the arc. When, as is commonly the case, special machines are used to supply arcs, and the load consists solely of arcs, the arcs would alter the character of the wave form. If the arc is replaced by a resistance, the wave form is of the same type as is obtained for the E.M.F. of the machine on open circuit.

The Society then adjourned till May 8th.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**(To-day) FRIDAY, May 1st.**

ROYAL INSTITUTION.

*5 p.m.* Annual Meeting.

INSTITUTION OF MECHANICAL ENGINEERS.

*7:30 p.m.* Ordinary General Meeting at 25, Great George-street, S.W. The following Papers to be read and discussed: (1) "Steel Steam Pipes and Fitting, and Benardo's Arc Welding in Connection therewith," by Samuel MacCarthy; (2) "Research Committee on the Value of the Steam Jacket; Experiment on a Locomotive Engine," by Prof. T. Hudson Beare and Bryan Donkin.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Chronographs and their Application to Gun Ballistics," by Colonel H. Watkin.

**MONDAY, May 4th.**

ROYAL INSTITUTION.

*5 p.m.* General Monthly Meeting.

SOCIETY OF ENGINEERS.

*7:30 p.m.* Ordinary Meeting at the Royal United Service Institution, Whitehall. Paper to be read: "Hydraulic Rotative Engines," by Arthur Rigg.

SOCIETY OF ARTS.

*8 p.m.* Cantor Lecture II.: "Applied Electro-Chemistry," by James Swinburne.

**TUESDAY, May 5th.**

ROYAL INSTITUTION.

*3 p.m.* Afternoon Lecture (I.): "Ripples in Air and on Water," by C. Vernon Boys, F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Ordinary Meeting. Papers to be read with a view to discussion: (1) "American and English Methods of Manufacturing Steel Plates," by Jeremiah Head; (2) "Four American Rolling Mills," by Samuel T. Wellman. At this meeting the monthly ballot for members will be taken.

**WEDNESDAY, May 6th.**

SOCIETY OF ARTS.

*8 p.m.* Ordinary Meeting. Paper to be read: "High Explosives and Smokeless Powder," by Hudson Maxim.

**THURSDAY, May 7th.**

IRON AND STEEL INSTITUTE.

*10:30 a.m.* Annual Meeting at 25, Great George-street, S.W. Various Papers to be read.

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Special Meeting. Fourth "James Forrest" Lecture: "Physical Experiment in Relation to Engineering," by Dr. A. B. W. Kennedy, F.R.S.

**FRIDAY, May 8th.**

IRON AND STEEL INSTITUTE.

*10:30 a.m.* General Meeting at 25, Great George-street, S.W. Various Papers to be read and discussed.

INSTITUTION OF JUNIOR ENGINEERS.

*8 p.m.* Meeting at the Westminster Palace Hotel. Paper to be read and discussed: "Notes on Belgian Electrical Engineering Practice," by A. Anstruther-Thomson and G. C. Allingham.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Electric Shadows and Luminescence," by Prof. Silvanus P. Thompson, F.R.S.

**SATURDAY, May 9th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

Students' visit to the London Electric Supply Corporation's Station at Stowage Wharf, Deptford.

**The Telephone Trunk Wires.**—On Thursday of last week the House of Commons resolved itself into Committee on the financial resolution upon which to found a Bill authorizing the raising of £300,000 under the Telegraphs Act, with reference to the purchase of telephone trunk lines. The resolution was agreed to. We understand that this £300,000 is to be spent over and above the million sterling authorised by the Treasury Minute of May, 1892.

# The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny.
Editorial, Publishing and Printing Offices,

**1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.**

*Telephone No.* 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

*All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher,* "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

*All Editorial letters to be addressed to the Editor.*

*All letters intended for insertion in* "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

**Subscription Rates.**—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | YEAR. | HALF-YEAR. | QUARTER. |
|---|---|---|---|
| United Kingdom ..... | 26s. 0d. | 13s. 6d. | 7s. 0d. |
| Postal Union ..... | 30s. 0d. | 16s. 0d. | 8s. 0d. |

(Post free, payable in advance.)

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

*Advertisement Rates, &c., forwarded on application to the Publisher.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* 4 *p.m. on Thursday.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications can be ordered direct of* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

**ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced).** Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

**ELECTROMAGNETIC THEORY.** By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

**THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE.** By Dr. J. A. FLEMING.

**VOL. I.**—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free.

**VOL. II.**—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

**ELECTRIC LAMPS AND ELECTRIC LIGHTING.** By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

**MAGNETIC INDUCTION IN IRON AND OTHER METALS.** By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

**ELECTRIC MOTIVE POWER.** By A. T. SNELL. 10s. 6d.

**THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical).** By Dr. GEORGE GORE. Price 10s. 6d., post free

**ELECTRO-CHEMISTRY.** By Dr. GEORGE GORE. Price 2s., post free.

**PRACTICAL NOTES FOR ELECTRICAL STUDENTS.** By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free

## SPECIAL NOTICE.

**Last week's number of "The Electrician" completed Volume XXXVI. With this week's number is issued (Gratis) the Index to the Volume.**

**NOW READY.**—Vol. XXXVI. of "THE ELECTRICIAN," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

The published price of Volumes previous to Vol. XXXVI. is 12s. 6d. post free 13s. 6d. Many of these Volumes are very scarce.

## ARCS AND WAVE-FORMS.

The various branches of electrical engineering have a curious tendency to complicate themselves by opening out from time to time into fresh ramifications and endless new developments. This, to a large extent but not wholly, is due to lack of finality. When electric supply, for example, has become crystallised into settled methods, it is only reasonable to expect that there will be fewer systems, while, on the other hand, it is scarcely probable that it will run in a single groove, as is the case with, say, water supply. There is an intrinsic versatility in things electrical, which gives us our different systems of generation and distribution, our various methods of electric traction, our continuous, alternating and polyphase currents, and, lastly, our complex array of wave-forms of periodic currents and electromotive forces. In these last examples lie recent and unusually startling complications, the discovery of which opens out new vistas of possibilities in theory and practice. The alternate-current arc, already the cause of many a battle among both theorists and practical engineers, now shows that, in certain circumstances, it possesses the remarkable power of adapting and distorting every form of alternate current wave with which it may be supplied, until it has "licked it into shape" to its own best advantage. In other words, the alternating arc can create for itself the most economical and efficient form of current wave out of any form of wave with which it may be supplied. This seems too good to be true; but if true it should be of tremendous value to the optimistic philosopher. What an argument for his "best of all possible worlds" it would have

Digitized by Google

proved for LEIBNITZ! Nor will optimist philosophy solely reap the benefit. A new light will be thrown on alternate-arc practice, and it is possible that this mode of electric lighting may receive fresh vitality to enable it to combat its rival of the continuous current.

It is to some researches by Mr. J. FRITH, the results of which are embodied in a Paper on "The Effect of Wave Form on the Alternate-Current Arc," which he read last Friday before the Physical Society, that we are indebted for this new insight into the behaviour of the alternating arc. Incidentally we may observe that the researches deal much more with the effect of the arc on wave-form than with the contrary. To grasp the full significance of Mr. FRITH's deductions we must look back at some researches of previous investigators. Scarcely had subsided the tumult of voices which, in 1894, arose in America at the suggestion that a sine-wave alternator was not the highest *desideratum* in that class of machinery, when an important Paper was read by Herren RÖSSLER and WEDDING before the Verband Deutscher Elektrotechniker on "The Potential and Current Curves of Different Types of Alternators, and their Influence on the Candle-Power of Alternate-Current Arcs." A translation of this Paper appeared in *The Electrician*, Vol. XXXIII., pp. 523 and 539. These investigators took three different makes of alternators, giving a flat-topped, a simple periodic and a peaky wave respectively; and, so far as their researches relate to arcs, they found that the highest luminous efficiency was reached with the flat-topped wave, and the lowest with the peaky wave; while, on the other hand, the arc was much more noisy in the former than in the latter case. Only one conclusion seemed at the time to be possible—viz., that for running arc lamps the best types of alternator were those which gave flat-topped waves, and it was generally assumed that dynamo builders would take this lesson to heart and design their alternating "arc-lighters" accordingly.

The conditions of a laboratory experiment often differ so widely from those in commercial practice, that it is impossible to apply practically the conclusions to which the experiment leads. This, it would appear from Mr. FRITH's work, is the case so far as RÖSSLER and WEDDING's researches relate to public arc lighting. For in those researches a large part of the output of the alternators was absorbed by a choking coil in series with the lamp, while in practice this is not the case. We are not ignoring the fact that it is common practice to put choking coils in series with arc lamps run off ordinary supply mains. But our remarks refer more particularly to circuits specially intended for arc lighting. It is only when the arc or arcs constitute substantially the whole load on the alternators that the current wave is distorted into its most serviceable form for lighting. If there is inductive or non-inductive resistance in series with the arcs they are partially or completely crippled in their effort to distort the wave. Thus it happens that when an alternator is employed to run a load consisting wholly of arc lamps, it does not matter what form of electromotive force wave the alternator might develop on open circuit or on a load of incandescent lamps. All types of alternators appear for such a purpose to have equal efficiencies, as regards wave form. Thus, too, it must follow that in all those researches which have recently been made on alternating arcs where the arcs have been run in series with several ohms resistance, the conclusions which have been drawn as to efficiency are not the happiest nor best that might have been. As Mr. FRITH says, in reference to one particular example, a type of wave which is not the most efficient is *forced* upon the arc.

There is still, however, a considerable element of uncertainty as to the general applicability of Mr. FRITH's deductions. The alternator with which he experimented was of an iron-core type, and it is just possible that the presence of iron in the armature core gave to the alternator and arc that power of interaction which made possible the curious distortion of the current and P.D. waves. It is conceivable that in an air-core or non-iron core alternator this reaction would be impossible, or would become reduced to an insignificant magnitude. But, should it turn out that, under the same conditions of load as in Mr. Frith's case, both iron-cored and non-iron cored alternators are appreciably affected by the arcs, we may expect that some modifications of arc lighting practice will result. For example, since arcs run from transformers on a general system of distribution would be unable to twist the wave to their best advantage, while arcs in series on a separate machine would be able to do so, preference for the latter practice would be strengthened, and all the more since the flat-topped P.D. wave is the very worst with which to feed transformers. It remains, in fact, to be seen what influence this new development will exert on arc light practice, but, whether it be great or little, the interest in the development itself is more than usually deep.

## REVIEWS.

**Handy Guide to Patent Law and Practice.** By GEORGE FREDERICK EMERY, LL.M., Barrister-at-Law, &c., &c. (London: Effingham Wilson. 1896.)

The learned author of this little volume has compressed within the limits of some 300 pages all the law and procedure relating to patents, even to a table of cases, a list of fees payable, copies of the regulation Patent Office forms, and an index, commendable alike from the point of view of typography and arrangement.

In a brief introductory chapter Mr. Emery gives the simple philosophy of our now sadly-complicated patent law. He shows how from an early period the Crown has possessed the power of granting to the inventor or introducer of a new industry the sole right of carrying on that industry for a limited time; how under "good" Queen Bess that privilege was shamefully abused to the profit of Court favourites, and how, as a natural consequence, the power of the Crown was regulated and curtailed at the first opportunity, the foundation of patent law proper being 21 Jac. I., c. 3., more commonly known as the "Statute of Monopolies." The origin of our present system is further revealed by the fact that even in this year of grace the grant of a patent is nominally an act of grace on the part of the Crown.

Unlike the writers of many manuals of patent law, Mr. Emery does not hold out, directly or by implication, visions of "wealth beyond the dreams of avarice"; on the contrary, he is laudably anxious to damp the ardour of the enthusiast possessed with an evil genius for aimless inventing. "The profit arising from an invention is not proportionate to the difficulty of making it," "it is often far easier to make an invention than to make it a commercial success," are samples of the deterrents scattered up and down this little work.

In the succeeding chapters the author deals with the subject-matter of letters patent, the procedure to be observed in obtaining a patent, the draughting of specifications, the grounds of opposition to a grant, the rights of patentees and licensees, the amendment of specifications, infringement actions, threats, extension of letters patent, &c. The subject is treated with such lucidity and method throughout that it is not too much to say that a careful perusal of Mr. Emery's book cannot fail to give a reader of average intelligence and education a good working grasp of the intricacies of English patent law and practice. What these intricacies are cannot be better illustrated than by the law relating to licensees *vis-à-vis* of licensors. A licensee, we are told, "is estopped from disputing

Digitized by Google

the validity of the patent, and, while he is paying royalties, is not at liberty to deny the title of his licensors." But he may allow his royalty payments to get in arrear, or he may repudiate his agreement, and in either event can by hook or by crook succeed in doing that from which he was originally debarred. All these turns and twists, so dear and so profitable to the legal profession are, it may be, inevitable offsets to the blessings of any system of law. The following sentence, however, which concludes the chapter on costs, tends to show that the disadvantages of law are to-day, as in the days of Justinian, in considerable danger of more than counterbalancing the advantages. "The result is that both parties often feel that it will be less onerous for them to put up with injustice than to enforce what they believe to be their just rights; the patentee allows infringement to pass unchecked, or accepts a lower royalty than he feels that he is entitled to, and the manufacturer pays royalties under what he believes to be an invalid patent, because each fears the unknown volume of extra costs which he will have to pay, even if he is completely successful in asserting his rights."

Mr. Emery has succeeded in admirably explaining this deplorable state of things; perhaps he would add to our indebtedness by suggesting a radical practical remedy.

## PUBLIC LIGHTING BY ARC LAMPS.*

BY ANDRÉ BLONDEL.

*(Continued from page 856, Vol. XXXVI.)*

### Experimental Comparison Between Different Types of Globes used in Public Lighting.

It is interesting to compare the various apparatus just described, from the point of view of the utilisation of the light of a continuous-current arc. Having regard to the restricted action of most reflectors in use, and the fact that polygonal lanterns are little used, I shall confine this comparison to that of divers types of globes. For this comparison, I have myself carried out, and also had carried out for me at the Central Electrical Laboratory, 12, Rue de Staël, [45] many series of photometric measurement, to determine the curves of distribution of the luminous intensities produced in the various directions by the arc; first, without globe, then with its globe. The arrangement invented to carry out these tests is described in another article. [46] It has the advantage of simplicity, and also avoids the errors of observation usually present in the comparison of lights of different colours. The curve of intensities has been drawn for each lamp, taking one of its intensities as a provisional unit. Then, to compare the various curves with each other, the maximum intensities of each have been compared; and, lastly the results have been reduced to a known standard by replacing the lamp under test by a carcel lamp. In this way the curves of distribution have been obtained for the naked arc, then for the arc placed in four different types of globe: roughened glass, opaline, opal, and holophane. The results thus obtained for a lamp taking 11 amperes are reproduced together in Fig. 50, I., to which has also been added the curve, recently published by M. Marechal, [47] for a 10-ampere arc in an opaline globe, but brought to the same scale as the results for lamps of 11 amperes by increasing it in the ratio 11/10. These curves give all the information necessary for the preparation of a scheme of lighting, according to the principles enunciated in the first portion of these articles. In addition, they show at a glance the widely different effects produced by different globes. To judge by the general aspect, we see that the clearest globes give the best distribution, and that the holophane globe has a form of curve which is both new and more advantageous than the others, seeing that with it the maximum is in a more oblique direction—65deg. instead of 45deg. This curve closely approximates to the type of which the advantages have previously been shown, [48] and its only fault is that it allows too much light to be sent upwards. This doubtless arises partly from the faults in the manufacture of the upper mirror, but more especially from the effect of the top opening through which the carbon-holders pass.

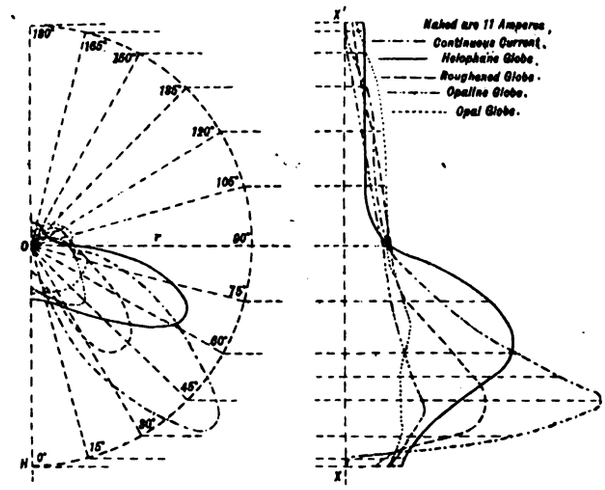

Fig. 50.—Comparison between the Photometric Curves and Curves of Flux of a Continuous-current Arc Lamp taking 11 Amperes under Different Globes. I. Photometric Curves. II. Corresponding Curves of Flux.

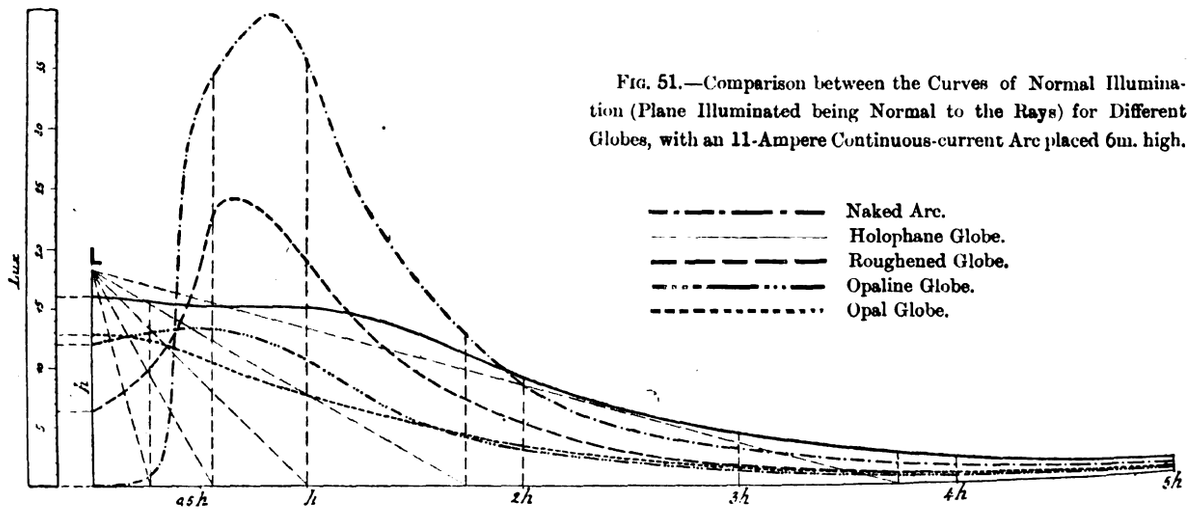

Fig. 51.—Comparison between the Curves of Normal Illumination (Plane Illuminated being Normal to the Rays) for Different Globes, with an 11-Ampere Continuous-current Arc placed 6m. high.

To make the comparison more precise, we will calculate the luminous flux and the illumination from the curves.

*Luminous Flux Utilised.*—The luminous flux is calculated by constructing the curve of flux from the curve of distribution, as explained in my "Theory of Public Lighting" (Fig. 50, II.). The abscissæ being calculated in *pyrs*, the area of the curve of flux multiplied by $\frac{2\pi}{r}$ gives the total luminous flux in *lumens* The figures in Table I. are arrived at in this manner. These results, which are closely in agreement with those of the other observers already quoted, clearly show the superiority of dioptric diffusion

* From *La Revue Technique*. Translated by Mr. John Hesketh.

[45] Thanks to the kindness of M. der Nerville, Directeur du Laboratoire, who, with the assistance of M. F. Guilbert, then chief of works, made the photometric readings relating to the holophane globe and the naked arc.

over ordinary diffusion from the point of view of absorption. We shall see that this is also the case from the point of view of distribution of the illumination.

rise to a superabundant horizontal illumination. For we may consider as useless any illumination above 10 lux. From a distance equal to the height, the illuminations decrease very unequally for

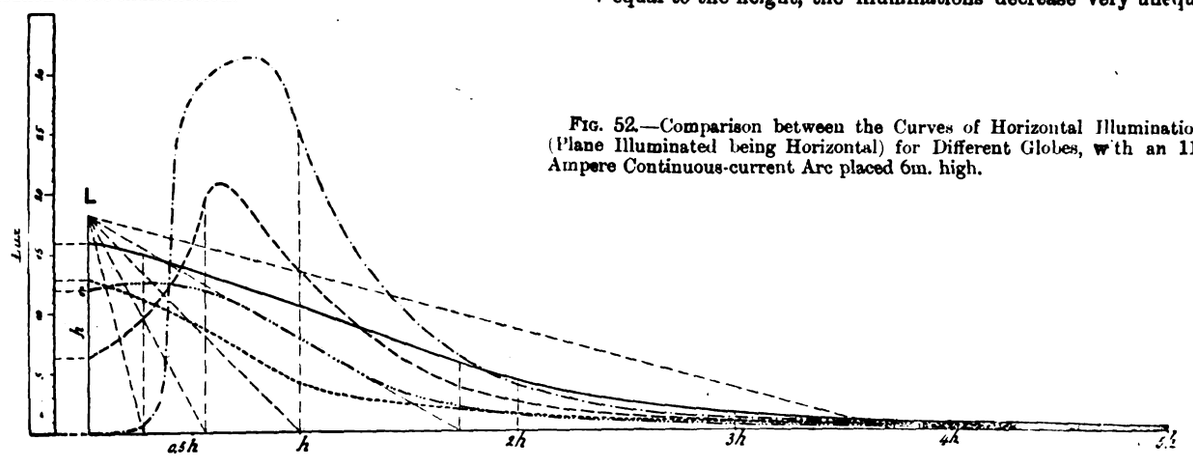

FIG. 52.—Comparison between the Curves of Horizontal Illumination (Plane Illuminated being Horizontal) for Different Globes, with an 11-Ampere Continuous-current Arc placed 6m. high.

*Curves of Illumination.*—The curves of illumination deduced from the polar curves are shown in Figs. 51, 52 and 53. In these the abscissæ are graduated in terms of the height, and a scale of illumination in lux has been drawn, corresponding to the case where

the various globes, and here the holophane globe shows a marked superiority, which increases with the distance, over the others. For instance, at the distance $3h$, the horizontal illumination, with a holophane globe, is 1·36 lux, while with the opaline and the naked

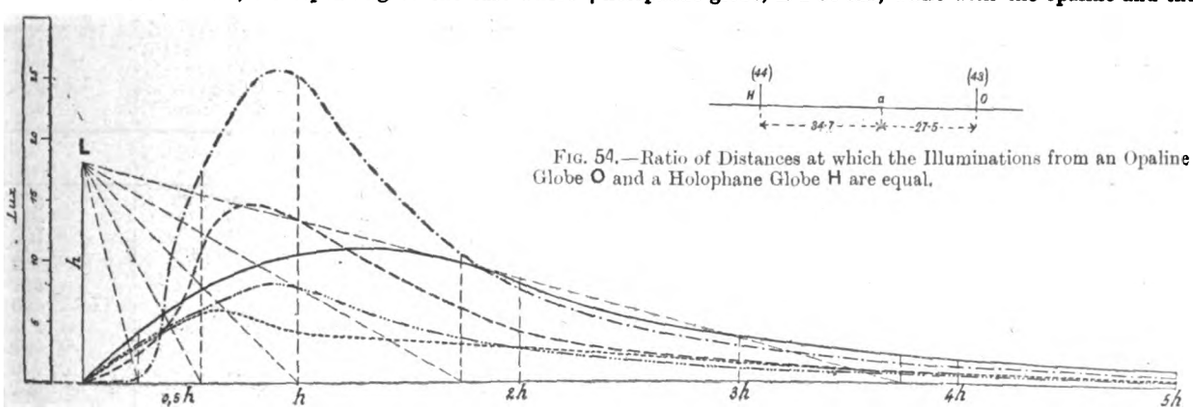

FIG. 53.—Comparison between the Curves of Vertical Illumination (Plane Illuminated being Vertical) for Different Globes, with an 11-Ampere Continuous-current Arc placed 6m. high.

FIG. 54.—Ratio of Distances at which the Illuminations from an Opaline Globe O and a Holophane Globe H are equal.

$h$=6m. In other heights, it is only necessary to alter the scales as indicated in the "General Theory of Lighting" (see *The Electrician*, November 8, 1895, p. 40). These curves all apply to 11-ampere

arc the illuminations are 0·42 and 0·98 lux respectively. This superiority has been confirmed in the experimental trials by the Edison Company with holophane globes placed between La Rue

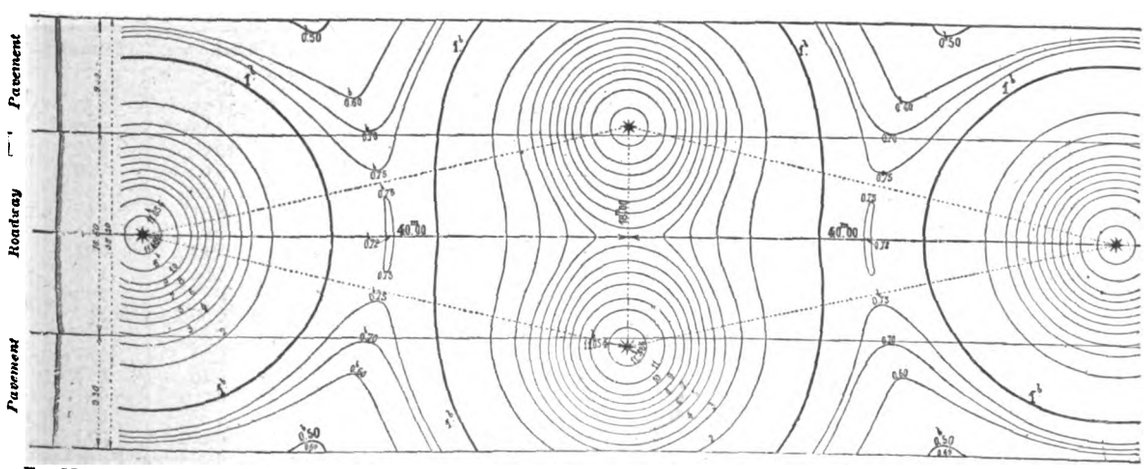

FIG. 55.—Plan of Illumination of the Grand Boulevards, Paris, with 10-Ampere-continuous Current Arcs, and Opaline Globes. Height of Arc, 5·95m. Figure taken from "L'Eclairage à Paris," by M. H. Maréchal.

lamps, placed successively in the different globes. Tables II. to VI. summarise the numerical data used in deducing these curves from the polar curves and the observed values. A separate figure has been given to each of the three illuminations, namely, that on the normal plane, that on the vertical plane, and that on the horizontal plane, which, as I have previously explained, give all the elements necessary for a scheme for lighting.

Examining these curves, we see that at short distances all classes of globes, including, despite its promises, even the holophane, give

d'Hauteville and La Porte St. Denis on the Boulevards Bonne Nouvelle and St. Denis.[49] By placing a shadow photometer between two

[49] At this moment there are 12 holophane globes in use on the Boulevards (between La Rue Hauteville and La Porte St. Denis) and on La Place de Roubaix. The Secteurs de la Transmission de la Force and the Edison Company have, in adopting these globes, given proof of a progressive spirit which is very rare in France, and does credit to the Directors. M. Weill and M. Meyer took the initiative in the matter, with the permission of M. Monmerque, the municipal engineer.

lamp posts, one of which was fitted with an ordinary opaline globe, and the other with a holophane globe, a very marked increase in the illumination in favour of the latter was observed, amounting to as much as 60 per cent. in the most favourable instance (Fig. 54). A similar result was obtained at Nantes (Place du Theatre) by the Societé Nantaise d'Eclairage, &c.

To properly appreciate the effect realised by the use of the holophane globe, the most precise method is to study comparatively the distribution of light on a given street with the same lamps, but with the two different types of globe: ordinary opaline and holophane. We will take as a basis for this comparison one of the plans prepared by M. Marechal (Fig. 55) corresponding to the lighting of part of the Boulevards with 10-ampere arcs and opaline globes of the ordinary type. Let us suppose the space lighted by the same arcs, but let them be fitted with holophane globes; and let us, under these new conditions, plot out isolux curves from the

curve of illumination of the holophane globe which is supposed to be fixed 6 metres high.[50] For this purpose it is sufficient to use the comparative curves of illumination on a horizontal plane (Figs. 57 and 58) determined for 10-ampere arcs 6 metres high with opaline and holophane globes. Fig. 56, thus obtained, gives us at a glance the effective result. The minimum illumination is raised from 0·5 to 1·25 lux, and the mean illumination from 3 35 to 5·36 lux. I have also prepared plans of comparative illuminations for the more usual case; that in which holophane globe is used on the Boulevards.[51] The curves thus obtained are reproduced in Figs. 59 and 60. The minimum illumination is raised from 0·33 lux to 0 88, and the mean illumination from 1·98 to 3 90 lux. The increase thus deduced from photometric curves is therefore seen to be very considerable.[52]

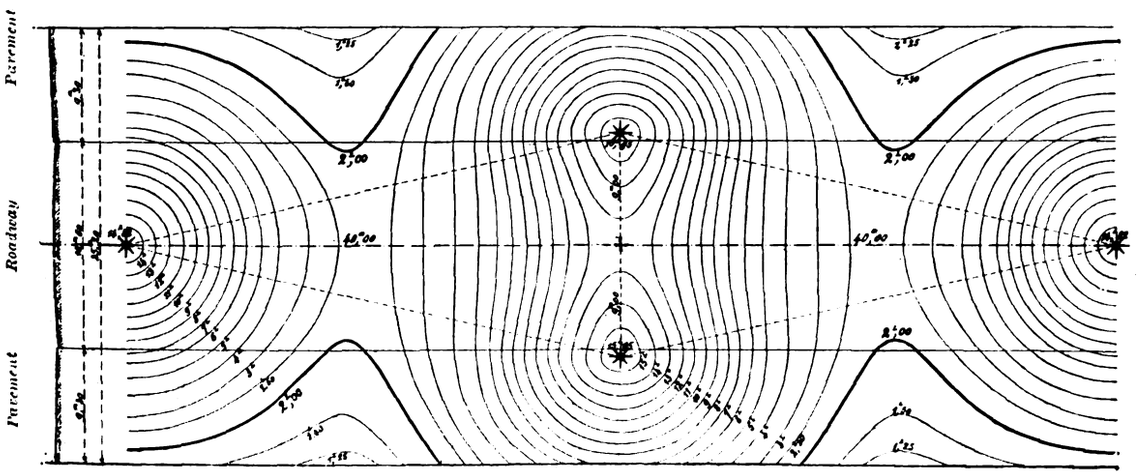

FIG. 56.—Plan of Illumination of the Grand Boulevards, Paris, with 10-Ampere Continuous-current Arcs and Holophane Globes 34cm. diameter and 6m. high.

I believe that it would be easy with dioptric globes to obtain a curve of distribution more nearly approaching uniformity; but, as

[50] The ordinates of the curve for the holophane globe have been reduced in the ratio 10/11 to bring the intensity of the lamp to the value (10 amperes) of that adopted by M. Marechal.

[51] These plans and curves of illumination have been designed by M. G. Rameau, civil engineer, who materially assisted me in the preparation of this work, and for whose excellent co-operation I wish to express my thanks.

[52] It is more difficult to appreciate the increase exactly by the eye, and on the ground; measurements should be taken with some instrument of

Digitized by Google

it was before stated, the time has not yet come for uniform illumination to be realised. We must wait until we have at our disposal a sufficient luminous flux to give a mean of 8 or 10 lux before attempting it. In short, we may conclude that the holophane globe actually approaches very closely to the conditions laid down in my "Theory of Public Lighting," and undoubtedly gives a better result than opal or opaline globes where constant-current arcs are used.[53] Two practical objections may, however, be made: First, the price is necessarily higher than that of opaline globes, in the manufacture of which there is no need of moulding or complex handiwork; and secondly, the division of the globe into two parts is objected to. The first is only serious at first sight. For if we calculate the annual expenses we see that the saving of 1 or 2 amperes, which

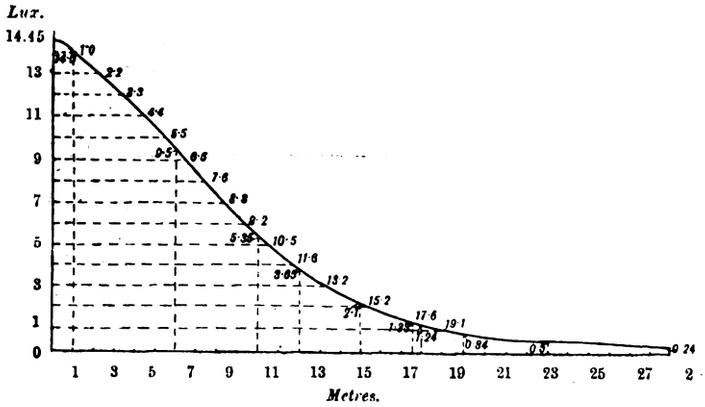

FIG. 57.—Curve of Illumination on a horizontal plane from a 10-Ampere Continuous-current Arc with Holophane Globe 34cm. diameter 6m. high.

we can straightway effect, results in an economy of more than 10 per cent. of the energy consumed, and the cost of the energy consumed constitutes the greatest item of the total cost. For instance, in Paris the cost being about 800f. per lamp per annum, the economy on this head alone would be 80f. in the first year; that is to say, more than would cover the cost and fixing of *many globes*. As to the division into two parts, experience on the Boulevards shows that there is no practical inconvenience with such a method of fixing as is in use in Paris (Fig. 25). It would nevertheless be

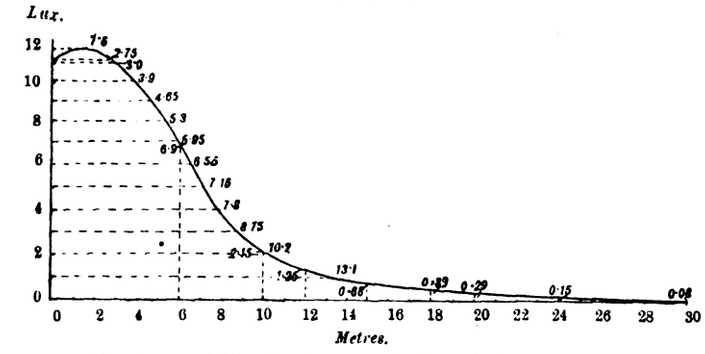

FIG. 58.—Curve of Illumination on a horizontal plane from a 10-Ampere Continuous-current Arc with Opaline Globe 34cm. diameter 6m. high.

preferable in many cases, in order to avoid the cost of cutting the globes, to use another type of support without hinges—allowing either the whole globe (as in Figs. 26 and 28)[54] or the lower half to slide up or down.[55]

*(To be continued).*

sufficient accuracy, and which may be placed on the roadway without interfering with traffic. Such an instrument has not yet been arrived at in France, and indeed those generally in use for measuring illumination more often indicate quite another thing. Mr. A. P. Trotter has invented a very ingenious photometer with which he has from actual observations made several complete plans of illumination, a result not previously attained by anyone. These plans have a very great value. I have, with the assistance of M. Broca, recently constructed a new universal photometer with the special object of enabling measurements of this nature to be made with accuracy.

[53] In this article I have only mentioned the holophane globe as applied to public lighting. These conclusions can also be applied to the other types of holophane covering.

[54] A similar arrangement has been adopted in the Grand Hall of the Cairo railway station, where the quays are illuminated in a very satisfactory manner by 18 Fabius-Henrion lamps, taking 24 amperes, and fitted with holophane globes.

[55] M. Oudry, Director of the Maison Durenne, appears to have satisfactorily carried out this arrangement.

## NOTES ON SOME AMERICAN ALTERNATING-CURRENT MACHINERY.*

### GENERATORS AND SYNCHRONOUS MOTORS.

Since all alternating-current generators can be used as synchronous motors, the two different classes of machines will be considered at the same time.

*General Electric Simple Alternators.*—These generators being designed for 125 cycles, are unsuitable for long-distance power distribution; since, however, transformers designed for higher frequencies are cheaper than those for lower frequencies, these generators have a wide field of utilisation for lighting and for limited power transmissions. Being simple alternators they are not self-starting when used as synchronous motors, but run very satisfactorily after being driven up to speed with external power.

The method of winding these generators is as shown in Fig. 1, each slot having two coils connected so as to give opposite polarity.

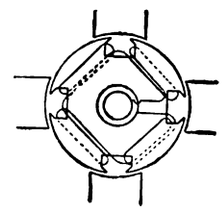

FIG. 1.

*Three-Phase Machines.*—Generators of this class are made in several types. That known as "A.T." comprises machines of uni-tooth construction, or having one slot per pole and phase, and having a moderately high armature reaction, and consequently great safety in case of short circuits. These machines are designed for any periodicity, but since the General Electric Company has adopted 60 cycles per second as its standard, by far the greater part of them are designed for this frequency. They are built in capacities from 50 kilowatts up to 1,200 kilowatts. This type, which is at present in considerable use throughout the country, is particularly applicable in places where power is distributed at moderately long distances, say 5 to 10 miles; owing, however, to the wave shape of these generators, which is of the saw-tooth type, they are not well suited for very long-distance transmissions. Up to 300 kilowatts they are usually built with a rectifying commutator for automatically compounding. The compounding is about 12 per cent. at full non-inductive load.

The accompanying diagram, Fig. 2, shows the method of connecting these machines. The armature has a Y-winding; that is, the three single-phase windings, which are displaced 120deg., or one

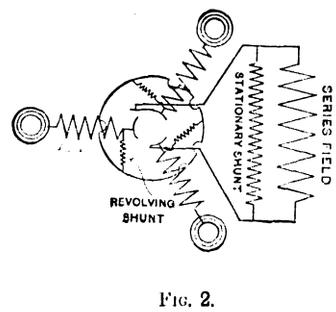

FIG. 2.

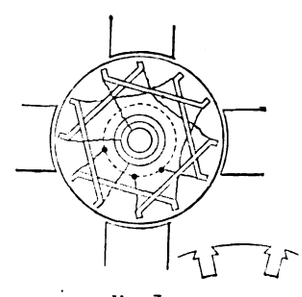

FIG. 3.

third of the distance between two poles, are connected to one common junction, which in this case is the commutator, and the other three sides are brought to the collector rings. The common connection is shunted by an external stationary and internal revolving shunt as indicated in the diagram. The object of these shunts is to give a means of regulating the amount of compounding necessary, part of the main current, 70 to 75 per cent., going through the series-coil and the remainder through the two shunts. The stationary shunt is made adjustable in order that the compounding may be varied with the different nature of the load. For instance, in the forenoon, when practically all the load consists of motors, a higher compounding is necessary than in the evening, when the lighting load is predominant. Another object which the shunts accomplish is to eliminate sparking at the commutator.

Fig. 3 shows the shape of the armature punchings and the method of winding. As will be seen, the winding is exceedingly simple, consisting of merely three single-phase windings displaced 120deg.

* Abstract from the *Electrical World* of New York. We are indebted to our New York contemporary for the blocks illustrating this article, which gives a useful insight into American methods.

The coils are made in two different shapes, and are machine-wound, so as to make it easy to replace one coil in case it is damaged by any cause. The slots are open, which decreases the self-inductance and, consequently, the amount of compounding for the same armature reaction. To prevent eddy currents in the pole-pieces

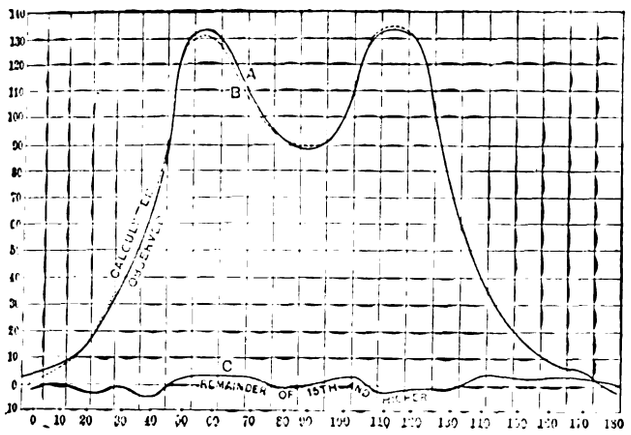

FIG. 4.

these are made of sheet iron. The yoke is made of cast iron to enable it to respond quickly to the magnetisation of the series-field.

Fig. 4 give the Y-E.M.F. of a standard "A. T." machine at no load, and Fig. 5 the Y-E.M.F. under load. In the no-load curve (Fig. 4) a distinct triple harmonic of 12 per cent. magnitude, and a very distinct fifth harmonic of 23 per cent. magnitude, are present. In

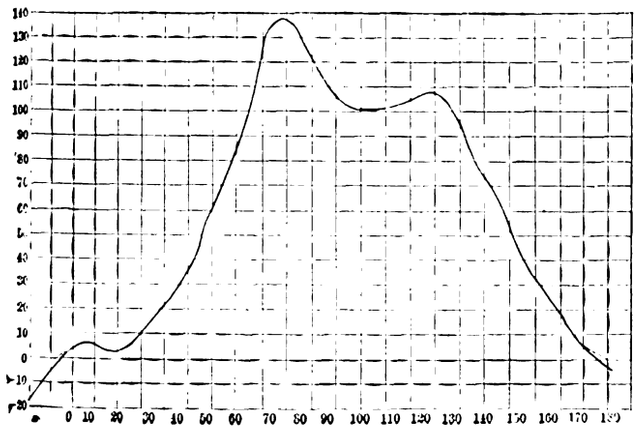

FIG. 5.

the load curve (Fig. 5) the triple harmonic is about the same as in the first case, it being 17 per cent., but the fifth harmonic is greatly decreased, being only of 8 per cent. magnitude.

The Δ-E.M.F.'s—that is, the E.M.F.'s between the main collector rings of the same machine—are shown in Figs. 6 and 7. Fig. 6 gives the shape of the no-load E.M.F., and Fig. 7 the shape of the E.M.F. under load. Both curves can easily be obtained from Figs. 3 and 4, as each is the sum of two of these waves displaced 60deg.

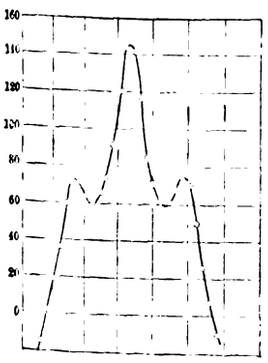

FIG. 6.

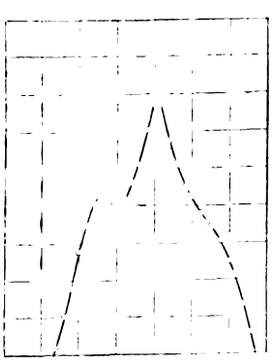

FIG. 7.

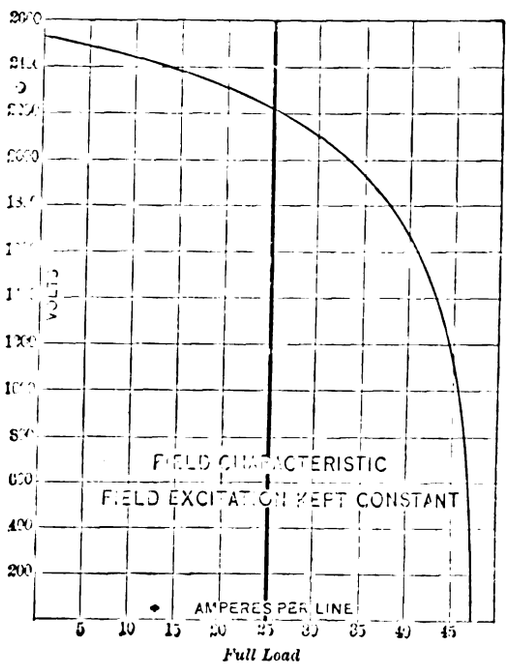
Fig. 8 gives the field characteristic of a standard "A.T." generator. As will be seen, at constant full-load excitation the drop in voltage at full load is about 12 per cent. The short-circuiting current is not quite twice the full-load current. The maximum momentary power at short circuit is only 18 per cent. more than full-load power.

A modification of these machines is the "A. F. T." type, having a non-overlapping fractional pitch winding. These machines have a very simple winding, with no crossings whatever, and consequently are of a very suitable construction for high-potential armatures.

For transmission of power to very long distances, the "A. T." machines are not so suitable, as the possibility of resonance is greater with the saw-tooth type of E.M.F. curve than with the sine type. The General Electric Company has, therefore, designed another line of machinery, known as the "A. P." which has a distributed winding, and is of the multi-tooth type of construction.



*Full Load*

FIG. 8.

These machines are mostly built for low potentials, say 500 volts, as there are a number of crossings in the winding, as may be seen from Fig. 9. They are usually built with two or three slots per pole and phase; that is, the number of slots is usually six to nine times the number of poles. The slots are open, and each has two rectangular conductors. They have a very low armature reaction so as to make it unnecessary to compound them, the total drop at full load being only a very few per cent. They are connected either Δ or Y, depending upon the voltage required, and are generally used in connection with step-up transformers.

As synchronous motors they are self-starting from rest; in starting they take a current two or three times that at full load, and start with moderate torque. Figs. 10 and 11 give the form of

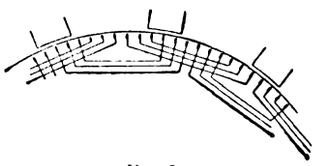


FIG. 9.

E.M.F. curves of one of these machines, which it will be seen, are practically sine waves—at least within error of observation, the greatest deviation amounting to only 2 per cent.

The field characteristic of an "A. P." machine of 75 kilowatt capacity is shown in Fig. 12. It will be observed that at full load the drop in potential at constant full-load field excitation is fully 4 per cent. The current at short circuit is about four times the full-load current. The maximum output is about twice the full-load power. This class of machines has the advantage of better regulation, and of giving the sine form of wave shape for long-distance transmissions.

*Monocyclic Machines.*—Three-phase generators are preferably used in places where the power is mostly utilised by motors. For cases where the current is mainly used for lighting, the General Electric Company has devised what it calls the monocyclic system. A greatly unbalanced load on the three branches of the three-phase or other multiphase system will cause the potentials between the different phases to vary. Monocyclic generators were brought out

Digitized by Google

a year or two ago to solve the question of running motors from single-phase mains, thus enabling compounding to be effected for the total output of the machines. The monocyclic generator is simply a single-phase generator with a slightly different armature, the monocyclic armature having a small winding, called the "teazer" winding, connected midway between the main coils. The object of this teaser winding is to supply an out-of-phase E.M.F. for use in starting and running motors only. This auxiliary winding creates an E.M.F. displaced 90deg. from, and one fourth the magnitude of, the main E.M.F. as shown in the diagram. At no load on the generator the value of the voltages between the outside of the tesser winding and the terminals of the main winding is there-

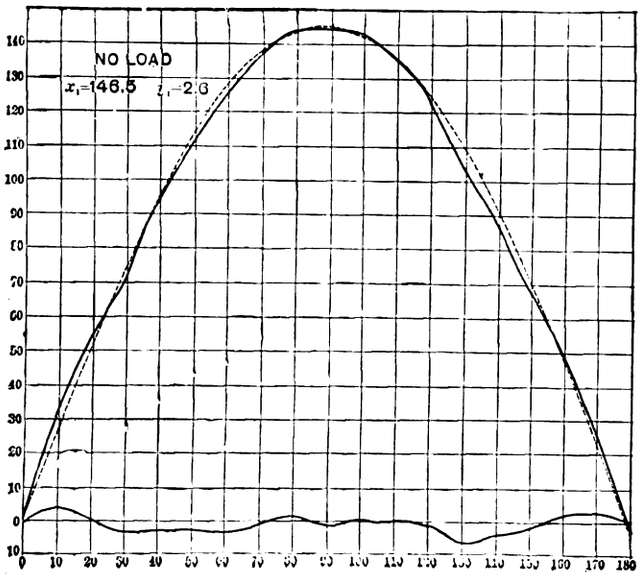

FIG. 10.

fore, say, 1,040 volts between the two main collector rings, and 580 volts between either of the two mains and the teaser (*see* Fig. 13). If the main line is loaded the induced E.M.F. is not in phase with the terminal E.M.F., but displaced a certain angle depending upon the self-inductance; consequently the triangle of E.M.F.'s, when the main line is loaded, is something like what is shown in Fig. 14, where, however, the magnitudes of the phase displacements are exaggerated. If the main voltage is, say, 1,040, the voltage between the teaser and one of the mains is 660, and of the other 480.

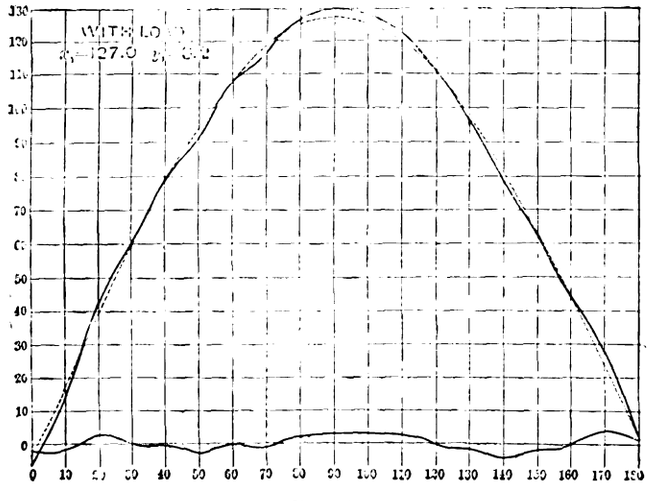

FIG. 11.

The effect of loading the teaser line, that is, of putting induction motors on the monocycle generator is to decrease the teaser potential and, on account of the self induction in the teaser circuit, to shift it; so that the triangle representing the E.M.F.'s at the terminals of the collector rings of the machines when the machine is supplying power as well as light, is something like that shown in Fig. 15. A discussion of the advantage of these changes of the phase relations will be given later when discussing induction motors operated on the monocyclic system. To run induction motors from a monocyclic generator, the E.M.F.'s generated by the machine are transformed to three other E.M.F.'s of approximately three-phase relation, it being, however, unessential to have the three-phase condition. Two-phase, or, in fact, any multiphase condition of E.M.F.'s can be got in a similar manner as the three-phase relation. To get three-phase E.M.F.'s two transformers are used. These have the primaries connected in series across the mains, and the secondaries reversed in their relation one to the other. The common terminal of the primaries is connected to the teaser line, and the three secondaries go to the motor terminals. Since the primaries of the two transformers are connected in series and the secondaries in multiple, the currents in two of the secondaries are smaller than in the third. The teaser wire of the primary practically carries only a magnetising current.

The proper sizes of the main and teaser wire may be approximately determined by the following method:—The main lines are calculated as for a regular, simple alternating-current system, taking, of course, not only the resistance but also the reactance of the line into account. Then the teaser-wire is made of such a cross-section that its ratio to the cross-section of the main wire is the same as the ratio of the total motor load to the total load of the machine.

The mains leading to each motor should be calculated as if the entire power of the motor were supplied through them only, and the teaser made of the same size. This method gives a cross-section somewhat too large, but one at least simple to calculate and safe. For the secondary wiring the total output of the induction motor should be figured as supplied by two single-phase mains with a common return; that is, one wire—that leading from the common connection of the transformers—should be made 50 per cent. larger than either of the other two, and the latter of such a cross-section as to carry jointly the total motor-power as a single-phase current.

All of the above machines—the simple alternators, the three-phase and the monocyclic machines—are usually built with revolving

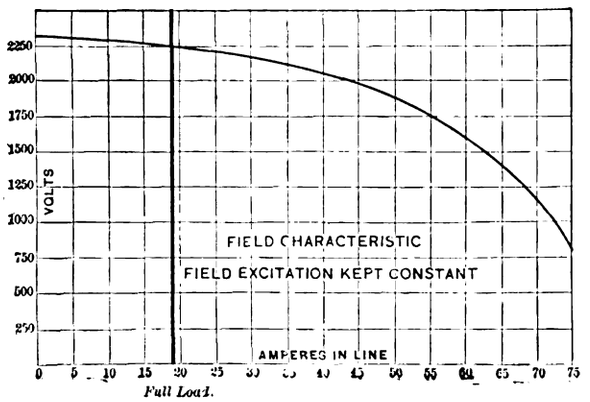

FIG. 12.

armature and stationary field. In special cases, as for very high voltages or very large currents, the machines are built with stationary armature and revolving field. In the latter case the field is inside, the armature outside.

*Calculation of Lines.*—In the continuous-current system the drop and the loss in the line may be readily obtained by simply multiplying the current and the square of the current, respectively, by the resistance. In the case of alternating-currents the matter is not so simple, since the drop is not only due to ohmic resistance, but also to the reactance. The resistance is practically the same whether the line be supplied with alternating or continuous current, but the reactance, which is zero when continuous currents are employed, has always a value in alternating-current systems. The reactance depends upon the frequency and the inductance, and is expressed by the following equation: $S = 2\pi N L$, where N is the frequency or the number of complete cycles per second, and L the coefficient of self-induction, or more properly, the inductance. This latter quantity depends upon the size of the wire and the distance between the conductors, and can be calculated for any given condition. The influence of reactance is very prominent when using heavy copper conductors in the lines. For instance, the reactance of No. 0000 B. and S. wire is 2·5 times its resistance, but with a No. 8 wire the reactance is but one-quarter of the resistance. This illustrates the advantage to be gained by the use in multiple of as many small conductors as possible instead of a single conductor. The reactance, as stated above, may be readily calculated for any given set of conditions, or may be obtained from several tables which have been published. Knowing the resistance and reactance, the drop due to each may be obtained, by simply multiplying each by the current. The impedance drop is the square root of the square of the ohmic drop plus the square of the reactive drop, or $E = \sqrt{c^2 r^2 + c^2 s^2}$, when $s$ is the reactance. The loss in the line depends

Digitized by Google

upon the resistance, and is expressed by $C^2R$. The reactance, being in quadrature with the current, does not represent a loss in power.

To make a complete and exact calculation of the conditions of current and E.M.F.'s in a long line is a complicated problem, but in general, very good approximate results may be obtained by several methods. The following is an example of the application of one of these methods. We will calculate a line suitable for supplying a 1,000-kilowatt three-phase power transmission with a distance of 10 miles, and at a difference of potential of 10,000 volts, employing 60 cycles per second. We will assume that the power factor of the load, which may consist of induction or synchronous motors and lights, is 90 per cent., or, in other words, the energy consumed is 90 per cent. of the total watts transmitted.

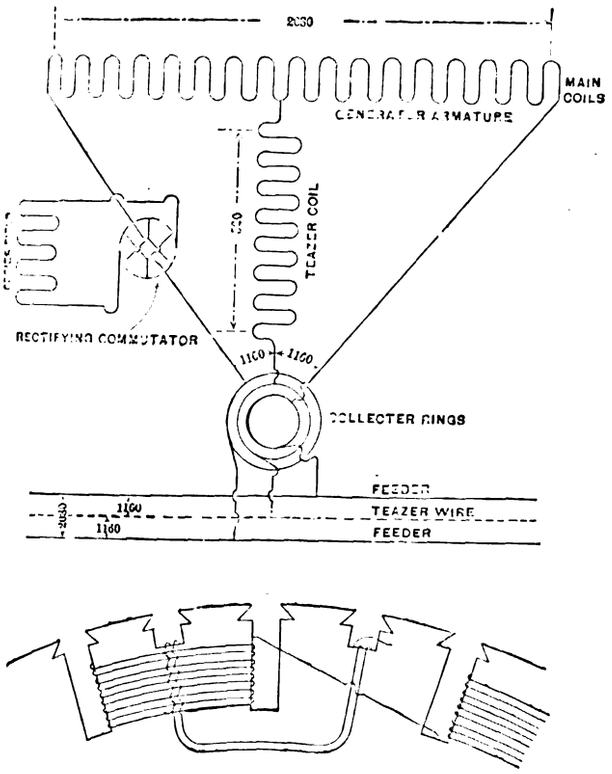

Fig. 13.

We will further assume that the step-up and step-down transformers each have a hysteresis loss of 1½ per cent., that the copper loss in each is ½ of 1 per cent., that the magnetising current is 4 per cent., and that the reactance drop is 4 per cent. Further, that the total loss in the power transmitted is to be 10 per cent. Since the total hysteresis and copper losses in the two transformers is 4 per cent., the loss in the line will be 6 per cent. The difference of potential at the generator between any two conductors will be $\frac{10,000}{\sqrt{3}} = 5,775$ volts. Consequently the energy current for each phase, that is, in each conductor, will be 58 amperes, since each phase is to supply 333 kilowatts. As 6 per cent. of the total volts is about

Fig. 14.

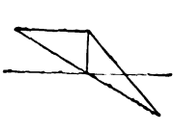

Fig. 15.

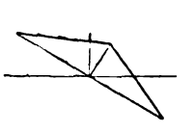

Fig. 16.

350 volts, the C R drop will be 350 volts. With a power factor of 90 per cent., the total current in each conductor will be $\frac{58}{0.9} = 64$ amperes. It follows that since C R = 350 volts, $R = \frac{350}{64} = 5.4$ ohms, or, since the line is to be 10 miles long, 0·54 ohms per mile. The resistance per mile of a No. 0 B. and S. wire is 0·518 ohms, and this, therefore, will be about the proper size to suit our conditions. The reactance of No. 0 wire, at 60 cycles per second, is seven-tenths of an ohm per mile, or seven ohms in this particular case. The C S drop, that is, the drop due to reactance, is $7 \times 64 = 448$ volts, or about 8 per cent. of the total voltage between two conductors. The energy voltage consumed in the two conductors is twice one-half of 1 per cent., or 1 per cent. As the energy volts consumed in the line is 6 per cent., the total drop in the energy voltage will be 7 per cent. The voltage consumed by the reactance in the step-up and step-down transformers will be twice four, or 8 per cent., and the reactive voltage consumed in the line, as calculated, is 8 per cent., and consequently the total reactance drop will be 16 per cent.

The energy current loss in each transformer, due to hysteresis, will be 1½ per cent., or for the two, 3 per cent. The wattless or magnetising current in the two transformers is 8 per cent. The percentage of the wattless current in the load, since the power factor is 90 per cent., will be $\sqrt{1-0.90^2} = 44$ per cent. Consequently at the generator the energy current is $90+3=93$ per cent., and the wattless current is $44+8=52$ per cent., and consequently the total current is $\sqrt{92^2+52^2} = 106.5$ per cent. of the current at the secondary terminals of the step-down transformer. Therefore the current at the generator is 6 per cent. larger than the current at the receiving end.

The energy voltage at the generator will be 90 per cent., which represents the power of the load, plus 1 per cent, which represents the ohmic drop in the two transformers, plus 6 per cent., which represents the ohmic drop in the line, giving a total of $90+6+1=97$ volts. The idle volts are 44 per cent., corresponding to the idle voltage of the load, 8 per cent. due to the reactive drop in the line, and 8 per cent. due to the reactive drop in the transformers, giving a total of 60 volts. Therefore the voltage at the generator is $\sqrt{97^2+60^2} = 114$ volts. The voltage at the generator has therefore to be 14 per cent. larger than the voltage at the receiving end. consequently the total volt amperes per phase at the generator will be 114 times 106·5, or 121 per cent., giving a power factor of only 82 per cent.

If the charging current of the line is to be taken into consideration, it being about 90deg. ahead of the impressed E.M.F., has to be subtracted from the wattless current due to reactance, which is about 90deg. behind the E.M.F. In this particular case the charging current is 0·17 amperes per mile, or 1·7 amperes in this line, which is 10 miles long, or, in other words, it is equal to 3 per cent. of the total current. The total actual idle current flowing in these lines is therefore not 52 per cent., but $52-3=49$ per cent. The total current will be $\sqrt{93^{-2}+42^{-2}} = 105$ per cent. instead of 106·5 per cent., as before found.

It is stated by the experts employed by the General Electric Company that transformers supplied with sine wave and non-sine wave E.M.F.'s give widely differing core losses. From actual tests it has been found that the difference in loss may amount to as much as 10 per cent. This depends upon the character of the flat topped wave. Since the maximum value of the flat wave is less than the maximum value of the sine wave of magnetisation corresponding to a sine wave-shaped E.M.F. and since the core loss depends upon the maximum magnetisation, the core loss is less with a flat wave than with a sine wave.

*Parallel Running of Alternators.*—The fact that it is the common practice both in this country and in Europe, to run alternators in parallel, leaves no doubt as to its feasibility, but naturally some types of machines are better adapted to this purpose than others. The smooth core machines are in some respects not as good as the iron clad, owing to the fact that a slight variation in the field excitation of one of the machines causes a very large cross current to flow between the two, thus loading them up with idle current. Further, if the machines are not completely in synchronism when thrown together, an exceedingly large cross current will flow when closing the switch. A machine having a very high self-induction is not suitable, as it will not allow a sychronising current to flow between the machines. Consequently the best sychronous motors or generators for parallel running, considered from a commercial standpoint, should have a moderate self-induction, that is, be of the ironclad type, and have a comparatively small armature reaction. The moment at which two single-phase alternators are in synchronism may be readily determined by connecting the secondaries of two transformers in series with one or more lamps, the primaries being each connected to one machine. Synchronism will occur when the lamps no longer glow.

In sychronizing three-phasers care must be taken to have all three phases in sychronism. The safest and simplest method of determining this is to place in series with each pair of legs a series lamp bank, and see when all three banks are dull. When this is the case the machines may be thrown in multiple.

When the potential employed is high it is better to use transformers. If the machines are self-compounding it is not sufficient to have only the mains of the machines connected in multiple, but also to have the series windings connected in multiple.

This can be done as shown in Fig. 17. If the commutator is put on to but one leg, great care must be taken in order to synchronise correctly, so that not only the three phases are synchronised, but also those two particular phases which have the commutators may be thrown together.

*Unbalancing of Alternators.*—A drawback in the polyphase distribution is the possibility of unbalancing the different circuits. Although this disadvantage is very much less marked than supposed

Digitized by Google

it does occur, but with reasonable care in the installation it will be hardly noticeable if the machines regulate well. It is impracticable to give any definite figures about the magnitude of this unbalancing, as it depends upon the type of machines used, the condition of the line, &c. To feel sure that no unbalancing will occur, it may prove desirable to follow the rule of distributing the load with the same care as in the Edison three-wire system, and no noticeable unbalancing will take place. In the monocycle system no unbalancing is noticeable, since all the load is on the same circuit, and this circuit is the only circuit on the machine. Unbalancing, however, whatever be the system, does not have a very serious influence on the potentials.

*Measuring of Alternating-Current Power.*—In the single-phase system the power supplied by a generator can readily be measured by means of a wattmeter having the current coil in one line and the potential coil between the lines. The total watts supplied by the generator are then directly read. The apparent output is the product of the current and the potential; the power factor of a single phase system is then found by dividing the wattmeter readings by the product of volts and amperes.

The power may be determined about as readily in the three-phase system as in the single phase. The first method that suggests itself is to employ three wattmeters, each having the current coil in one

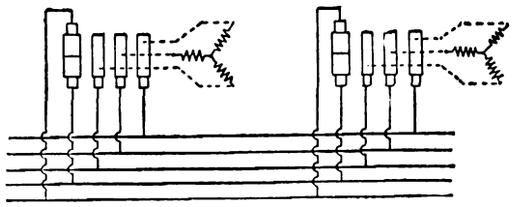

Fig. 17.

of the lines, and a potential coil connected between the three single phases. This method gives the full power, but since all alternators do not have the Y connection (which is necessary to give common connection) this method cannot always be used. Furthermore, it introduces the use of three wattmeters, which makes it rather complicated and expensive.

If the load is balanced in the three branches, the three wattmeters should read the same power, and consequently it would be necessary to use but one, and multiply the reading by 3. Another method of measuring the three-phase power is to use two wattmeters having their current coils connected in two of the lines, and the potential coils between these respective lines and the third line as shown in Fig. 18. If the power factor of the machine is more than 50 per cent., the wattmeters will read positive. If the power factor is less than 50 per cent., one of the meters will give negative readings. To get positive readings, one of the leads will have to be reversed. The total watts will, in the first case, be the sum of the two readings, and in the second case the difference. Instead of using two independent wattmeters, one wattmeter would suffice if this is provided with two armatures and two fields.

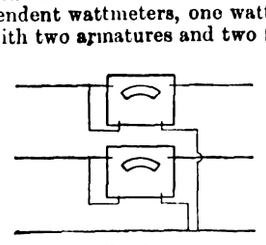

Fig. 18.

The third method of measuring the power is the use of an artificial neutral point. Three wattmeters have to be used if the load is unbalanced, and one wattmeter if the load is balanced. To get the artificial neutral points—that is, an artificial common connection—it is necessary to have three resistances connected together, each going from one of the lines, and of such magnitude that the total resistance of the three circuits (one including the resistance of the wattmeter) is equal. The total volt-amperes, that is the apparent power from the three-phaser is the product of the volts between the lines times the current in the lines times the $\sqrt{3}$—that is, $1{\cdot}73 \times$ volts $\times$ amperes. Consequently the power factor is $= \frac{\text{total watts}}{1{\cdot}73 \times \text{volts} \times \text{amp.}}$

In the quarter-phase system the power can be measured with a wattmeter in each of the individual circuits, as shown in the case of the single-phase system. If the circuits are equally loaded the total power will be twice the power in one phase; that is, twice the power that is read on one wattmeter, having a current coil in one of the lines, and a potential coil across the lines of the same phase. If the power is not equally distributed two wattmeters will have to be used. The total power is the sum of the two readings. The total volt-amperes, if the load is balanced, are twice the volts between the two mains of one phase times the current in that phase, or if the load is unbalanced the sum of the volts times amperes in each phase. The power factor is, as before, $\frac{\text{total volts}}{\text{total volt} \times \text{amp.}}$

*(To be continued.)*

## ELECTRIC TRAMWAYS AND TELEPHONIC DISTURBANCES.

With reference to Dr. C. S. Du Riche Preller's article on "Electric Tramways and Telephonic Disturbances," in *The Electrician* of January 10th, and Dr. V. Wietlisbach's article on the same subject in our issue of March 27th last, the *Elektrotechnische Zeitschrift* in its current issue makes some editorial remarks which may be of interest to our readers. The following is an abstract of our German contemporary's observations:—

"The opinion that tramways with slide contacts disturb telephone circuits less than those with trolley contacts was expressed some months ago by Dr. C. S. Du Riche Preller in an article published in *The Electrician*, in which he relates his observations made on the lines at Zurich, Geneva, Bale, Mulhouse, Havre and Marseilles. The contents of this article, however, shows clearly that there were no careful and thorough investigations, all the different tests being made in a very superficial way, which, in a case where important material interests are in question, must be strongly condemned. For this reason we abstained at the time from making any reference to the article, the author of which, however, received a sharp retort from Mr. E. Kolben in a letter to *The Electrician*. However, finding in Dr. V. Wietlisbach's article the same opinion expressed—namely, that trolley lines cause greater disturbances than tramways with slide contacts—we inquired, first of all, of the author of the article whether he based his opinions on Dr. Du Riche Preller's investigations, or whether he had arrived at the same results independently. To this Dr. Wietlisbach answered that the latter was the case, and that his investigations date further back than Dr. Du Riche Preller's. He further writes:—"It is now quite certain that all trolley lines do not produce the same amount of noise, as is shown, for instance, by the tramline at St. Moritz, which was constructed by Schuckert and Co., and which has given rise to very little telephonic disturbance. There is no doubt that a great difference exists in the telephonic disturbances caused by the different tramways, but the cause of it is not exactly known to me. The discovery of the real cause is rendered the more difficult since tramway companies will not permit conclusive experiments to be carried out on their lines." Undoubtedly the remarks of Dr. Wietlisbach in his article with regard to the elastic oscillations of the trolley wire are to the point, but in spite of this we cannot share his opinion that the principal source of disturbance lies in the contact of the collector and the trolley wire. If this view were a correct one, the tone of the noise in the telephone should change more markedly when the car passes curves than is the case, for the reason that the number of oscillations in the short sections of the trolley wire in the curve is different from those in the straight line. Instead of looking for the main cause of disturbance at the constant point of collector and trolley wire it appears to us obvious to ascribe it to the variations of the resistance between car wheels and rails. As is well known, the running of a car causes oscillations of high frequency in the rails and wheels, and the consequence is a corresponding variation of the resistance between wheel and rail. These variations of resistance will for obvious reasons, be far greater at curves than on the straight, without, however, acquiring a quicker succession. The increase of the noise in the telephone when a curve is passed is thus explained. In the same way the large difference in the disturbance caused by various systems, as mentioned by Dr. Wietlisbach, can be explained. The frequence and amplitude of the oscillations of the rails depend upon the size and the foundation of the rails. With regard to these factors, however, there exist among the various tramways large differences, which must have some influence on the disturbances in question. The increase in the disturbances during the first few weeks of the working of a tramway is, upon this supposition, easily explained. In the newly-laid rails the tightly-fitting foundation has a damping effect upon the oscillations. Gradually, however, the rails become loose, the damping is reduced, and the cause of disturbance increased. If this increase is less noticed on lines with slide contacts than on a few trolley lines, the cause of it should be put down to the accidental differences of the foundation, which, however, have nothing to do with the system of overhead construction. We made some experiments a few days ago on the Berlin-Charlottenburg line, and find the correctness of the above opinion confirmed. The details of these experiments will be published in our next issue."

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April 17, 1896.*

**The National Electric Light Association Electrical Exhibition**—The Exhibition which will be held in New York in connection with the annual meeting of the National Electric Light Association, promises to be one of the most successful exhibitions of this character that has ever been held, and second only to the great electrical display at the World's Fair at Chicago in 1893. Great interest is being taken in the matter, and the individual exhibits will be many and of an extremely interesting nature. Governor Morton, of New York State, will start the machinery in motion by closing a circuit with the same golden key that was used for the same purpose at the World's Fair by President Cleveland. It is proposed that when Governor Morton closes the circuit and starts the power machinery, he shall, by the same act, close a circuit from New York to San Francisco and back. Another interesting feature of the Exhibition will be the proposed transmission of electric current from the Niagara Falls power plant to New York, which current will operate Tesla two-phase apparatus in the Exhibition building. It is intended to further extend this idea by using long-distance telephones for the purpose of transmitting to New York the noise of Niagara Falls, thus heightening the realistic effect. Mr. Stillwell, of the Westinghouse Company, goes a step further, and proposes to deliver some of the Niagara Falls current to condensers for the purpose of transmitting signals through some of the Atlantic cables to England and Europe. If the latter idea is carried out, therefore, it is probable that our friends in London may receive telegrams transmitted across the ocean by some of the transformed power of Niagara Falls. At this Exhibition Mr. Edison will make a great display.

**The Application of Electric Power to Textile Industries.**—An interesting application of electricity has recently been made by the General Electric Company in the mills of W. J. Dickey and Son, Baltimore, Md. A horizontal water-wheel is belted to two 90 H.P. moderate-speed generators, and the current is transmitted about 200ft. to the third story of the woollen mill, where it is to be used to operate motors and furnish light. There are in this plant 36 60in. woollen cards and four mules are to be placed, the cards being arranged in three rows, 12 in each row, with a line of shafting for each row. Two of these line shafts will be operated by two 25 H.P. slow-speed motors, and for the operation of the mules a 20 H.P. moderate-speed motor will be connected to the shafting.

**Municipal Ownership of Electric Plants.**—It is proposed that the National Department of Labour and the Bureaus of Labour Statistics in the several states of the Union should take up as a subject for joint investigation municipal ownership of gas and electric light plants. Every electric and gas lighting plant in the United States which is owned by a municipality will be reported upon, and a sufficient number of private establishments will be included to afford a basis of comparison between the two classes of stations.

**An Electric Yacht.**—Mr. John Jacob Astor is having an electric auxiliary yacht built at Nyack-on-the Hudson. The boat will be 72ft. long, 12ft. wide, and with a draught of 4ft. She will be fitted with twin screws, which will be driven by electric motors. The two motors will aggregate 50 H P., and will derive their power from 480 cells of storage battery placed underneath the cabin floors. The motors will also be located under the floor, this arrangement giving the owner use of the entire space in the cabin. It is calculated that the yacht will be capable of developing a speed of 16 miles an hour. The craft will, it is needless to add, be handsomely fitted out.

---

**The Cost of Building an Electric Locomotive.**—By a curious coincidence, says the *Electrical World* of New York, the new Westinghouse-Baldwin locomotive weighs 160,000lb. and cost $16,000, which is just 10 cents a pound.

## CORRESPONDENCE.

### THE MELBOURNE MUNICIPAL ELECTRIC LIGHT STATION.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue dated January 31st you refer to the Melbourne City Electric Light Station in a manner which calls for a few remarks from me, which I trust you will be good enough to publish.

In Great Britain there is no station erected solely for street arc lighting of the capacity of the Melbourne plant, and, if there were one, I should like to know from you what design would have been adopted in the year 1891, when the Melbourne plant was designed. If you say that small unit engines coupled direct to dynamos of 50 arc light capacity each would have been economical, your opinion would be contrary to that of most of the engineers in America and on the Continent who have had experience in that class of station.

In Milan, which I visited in 1892, the engineer of the arc station of similar capacity to the Melbourne one, informed me that he was throwing out the high-speed engines then employed and installing instead four compound condensing engines of 300 I.H.P. to drive by countershaft the Thomson-Houston dynamos in use, and by that change he hoped to save 50 per cent. in the coal bill as well as a large saving in oil and other expenses. The first of these engines I saw in course of erection.

In America I can refer you to several arc plants which had in 1892 been quite recently erected and were identical in many ways with the one now in Melbourne. They were situated at Worcester, Mass.; Boston, Mass.; Chicago (three stations); Pawtucket, R.I.

From extended tests of the coal consumption at the Melbourne station I find that the coal per unit generated is 5·3lb., which compares very favourably with the Board of Trade returns from electric lighting stations in 1894, which, according to Prof. Unwin, taking only the largest and best stations, the consumption of coal varies in different cases from 7lb. to 12lb. per unit of electricity generated. The details of my tests above referred to I hope shortly to have the honour of forwarding to the Institution of Civil Engineers.

The cost of labour would be increased if the four large horse-power engines were replaced by ten high-speed of lower power. At present the engine, countershafting and separate condensing machinery attendants consist only of one engine driver and two greasers. If less attendance than this would be required with the other systems I would be very much surprised.

As to breakdowns, we have now been running for over two years, and have never had a cessation of the lights for one second. The Council ordered the gas lamp standards to be dismantled the week after the electric light was switched on. Repairs have been very slight, a fitter and a boy maintaining the whole plant in the station in thorough repair. As far as defects in the plant are concerned, including the 20 arc dynamos, only one hot bearing is the record for the two years.

If you, Mr. Editor, can mention a parallel case in which the Council of a city of 4,700 acres has entirely replaced the gas with arc and series incandescent lamps, where the whole cost of maintenance of the new light, including 4 per cent. interest on capital and 7½ per cent. depreciation, is below the previous cost of gas lighting, I shall be pleased to hear of it.

In a letter by Mr. Pardoe, published in a subsequent issue of your esteemed journal, a gentleman I do not remember meeting, but who kindly defends the system adopted, refers to the only plant in Australia he knows of in which the dynamos and engines are direct coupled, viz., the Hotel Metropole, Sydney. I may say I had the pleasure of installing that plant immediately after my arrival from the old country in 1889. I admit that the best system for incandescent lighting where the dynamo units can be obtained of larger capacity is that in which the engine and dynamo are direct coupled, especially when the load is a varying one, but where the load is constant and only small arc dynamo units are available, and

Digitized by Google

when water is convenient for condensing purposes, then by all means erect slow-speed compound or triple-expansion condensing engines, even if one has to use your *bête noire* a countershaft.

In conclusion, I would point out that had I desired to erect high-speed engines there would have been serious opposition by the ratepayers to the importing of them from home, as I would not be able to recommend their construction in the colony; a payment of 35 per cent. duty would also be a serious consideration.

The steam plant, although practically all manufactured in the colony, excepting the tubes and staggered headers for the boilers, is a credit to colonial engineering, but I am certain I would not be able to say that of the engines I would require for direct driving, the engine makers out here having no experience with that class.

I can only add that if I were asked to design a station for the same purpose as the Melbourne plant, with the same systems only then available and circumstaaces the same, I could not improve on the Melbourne plant.—Yours, &c.,

A. J. ARNOT, A.M.Inst.C.E.,
Electrical Engineer's Office, City Electrical Engineer.
Town Hall, Melbourne, March 10, 1896.

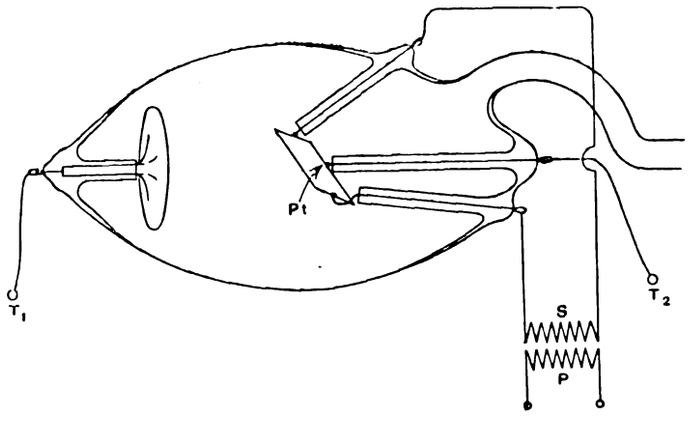
## RÖNTGEN RAYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It would be better, in these days, not to add too quickly to the sea of unclassified new results with the Röntgen radiation; but the following observation is communicated in the hope that it may prove of practical value in the use of Jackson tubes.

Convincing experiment has shown that *reversing the current in a focussing tube improves it for its normal working after "fatiguing" has set in.*

I am aware that this is in direct opposition to the instructions accompanying Newton's expensive little toy, and I hasten to add that the reverse current used should be comparatively weak.



Of late there has been some discussion as to the localisation of air layers, the "improvement" of the vacuum with use and the beneficial effect of heating the fatigued tube. It has therefore seemed that the revival due to reverse current is caused by the generation of heat in some particular part. If one could hold the fanciful idea that the air molecules were, by continued use, driven to a part of the tube where they remained sticking—then it would be a convenient hypothesis to assume that the reversal drove them back. But Tesla's statements regarding the unwelcome improvement of a long-used vacuum due to actual loss of air from the tube oppose the said fanciful idea.

It then occurs to one that a surface fatiguing of the platinum leaf may come in. The writer is, therefore, about to try the effect of leaving a current-flow in the platinum during the action of the tube.

The above figure explains itself. Uni-directional current rushes could be sent through S, and thus subject *Pt* to the conditions referred to.—Yours, &c., JAMES MARK BARR.

# LEGAL INTELLIGENCE.

## Electric Construction Corporation v. South Staffordshire Tramways Company.

This case came before Mr. Justice Romer in the Chancery Division on Saturday last, when

Mr. EVE, Q.C., in opening the case, said that the action was brought for the payment of sums of money due under an agreement entered into between the plaintiffs (the reconstructed Electric Construction Company) and the defendant Company in February, 1892. There had been a defence and several amended defences put in, but the last defence came to this, that the agreement was, under the circumstances, so tainted with fraud that the Court would not enforce specific performance. In their counter-claim the defendants set up that the agreement was not binding on them, and asked for rescission, other relief and damages. So far as the plaintiffs were concerned there was the admitted agreement and the execution, and one might rest there and leave the defendants to make out their counter-claim, but that would be obviously inconvenient, seeing that several persons who would be called as witnesses were accused of fraud, and, therefore, it was necessary to go into the matter and see what the agreement really was. The defendant Company was incorporated under a special Act passed in 1889, and were the successors of a limited company, which was incorporated in the eighties for the purpose of acquiring the benefit of certain Provisional Orders for the construction of tramways in Staffordshire and their maintenance. Under the Provisional Orders the tramways were made in 1883. The original idea was that some sections of the tramways should be worked by horse power and other sections by steam power. In 1888, after two years working by steam, the local authorities in the districts served by the tramways intimated they could no longer grant the licences for the working of the sections worked by steam unless the whole working plant and mode of working was altered. There was no doubt, therefore, that as early as 1888 the Company was told they must get some other system. Under these circumstances the limited company, which had raised all the money it possibly could, was at a loss to know what to do, and it was considered necessary or desirable that the limited company should be dissolved, and a statutory company should be formed for the purpose of acquiring the assets and liabilities of the limited company, and that, if possible, some other means of working should be devised. A Bill was accordingly formulated and passed in Parliament. The Company being face to face with the fact that the permanent way was out of order, their engines of antiquated construction, and there being difficulties in the way of the weight of the cars, had to set about seeing what form of motive power they should substitute for the steam power. At this time there had been introduced a system of working tramways by means of overhead electrical appliances, and on October 17, 1889, it was agreed to invite tenders for the supply of traction power and maintenance. In May, 1839, a company was registered for the purpose of introducing the system of electrical working into this country, and that was the plaintiff company in this action. This company was formed with a capital of half a million sterling in 50,000 shares of £10 each. Mr. Joseph Smith, who subsequently changed his name to Ebbsmith, was the Managing Director. Previous to 1883 Mr. Ebbsmith was a member of a firm of solicitors acting for the South Staffordshire Company, and he was the person who engineered the Bill through Parliament. The works director was Mr. Thomas Parker, and the engineering adviser of the Company was Mr. Carruthers Wain. By one of the amended defences it was supported that this Company was got up for the purpose of foisting the undertaking on the defendant Company or to bleed the defendant Company in the matter of the traction part of the undertaking. One of the equities relied upon against the plaintiff Company was that Mr. Spencer Balfour and Mr. Carruthers Wain were founders of the Company. The Company was floated, and ultimately the agreement of February, 1892, was made. In March, 1895, the plaintiffs, under a clause in the agreement, elected to determine, and if the notices given were valid then the plaintiffs were entitled to the sums they sued for and a declaration that they were entitled to determine the agreement.

His LORDSHIP asked if the defendant Company had been wound up.

Mr. EVE replied that it had not. When the petition came on the petitioners were paid off upon an understanding that the matter should be raised in an action.

His LORDSHIP said that in his opinion if the plaintiffs were so greatly interested it would have been to their advantage to carry on the business.

Sir F. LOCKWOOD, Q.C., for the defendants, said that he had already made an offer, and he thought there ought to be some *modus vivendi* that would put an end to the action.

At this juncture a consultation took place between the counsel engaged with a view to a settlement, but it was found impossible to come to an arrangement, and the hearing of the case was therefore continued.

Mr. EVE read the remainder of the correspondence which had passed between the parties, at the conclusion of which the learned counsel said that the plaintiff's case was this. Here was an agreement which was entered into from the beginning by two parties who were at arm's length. From the correspondence it looked as if both parties had been trying to make the best bargain they could for their respective Companies, and there was no suggestion of *mala fides* or over-reaching in respect of that. Under all the circumstances the plaintiffs claimed that they were entitled to recover the sums properly paid to them under the contract, having regard to the events that had happened. The difficulty that had weighed with him was that, suppose this contract was put an end to, the plaintiffs would still be entitled to be paid for the work done by them, which would amount to considerably more than the sum sued for.

His LORDSHIP here offered his assistance towards a settlement, but unavailingly. He asked Mr. Eve what relief he sought?

Digitized by Google

Mr. EVE replied that he asked for an account of what was due in respect of the mileage during the working of the tramways; that they were entitled to determine the contract; that they were no longer bound by clause 8 of the contract, which provided that for a period of five years they should manage the work, and inasmuch as the mileage for five years on 250,000 was a portion of the price payable to the plaintiffs, and by reason of the determination of the contract they were not able to receive that price, they asked for the difference between the actual mileage run and the minimum mileage in five years, namely, £13,186, being 4½d. per mile. The defendant's answer to that was that the agreement was over-reaching and ought to be set aside, in respect to which they counter-claimed.

Evidence was then called in support of the plaintiffs' case.

Mr. JOHN I. COURTENAY, a Director of the plaintiff Company and formerly a Director of one of the companies which the plaintiff Company was formed to take over, said he was always opposed to the contract in question, as it was a lock-up of capital and the South Staffordshire Company had no money, though he was always desirous of making use of the patents they had in order to show what could be done for electric traction in this country. Jabez Spencer Balfour and Ebbsmith were promoters of the plaintiff Company, and Ebbsmith was a strong supporter of the contract. Mr. Parker, the engineer, was in favour of the contract, and witness was eventually won over because it was proposed to issue debentures. It was not true that the details of the contract were discussed and arranged between Mr. Ebbsmith as Managing Director of the plaintiff Company and Mr. Wain on behalf of the defendant Company. The preliminaries were so discussed and arranged, but the details were gone into by the Board. He regarded the contract as an advantageous one for the South Staffordshire Company, but he would not say they could not have survived without it. He had read a report of a trial in which it was said that Ebbsmith and Wain had fraudulently conspired against the South Staffordshire Company. After Ebbsmith ceased to be Managing Director of the Company, he had no more authority for a contract than an ordinary director had. With regard to the debentures, it was not anticipated from the first that they would find their way into Mr. Ebbsmith's possession, but ultimately they did do so. The reason he was apprehensive that the defendant Company could not carry out the contract was that they had no capital, and it meant the locking up of such capital as there was.

Mr. ALFRED DICKINSON said that in 1883 tramways then existing were worked by steam and horse-power. In 1889 complaints were made by the local authorities respecting the permanent way, and consequently in June, 1891, he went to America, at the instance of the defendant Company, to inquire into the electric traction systems of that country, and he reported in favour of its adoption by the defendant Company. He had left the defendant Company, and was now in the employ of the plaintiff Company at a salary of £300 a year. The Dickinson Appliance Company was formed for financing and working patents witness had invented. Mr. Ebbsmith was practically that Company. He knew nothing of the transactions between Ebbsmith and that Company at the time, but had since learned that Ebbsmith sold the patents to the Company for a greatly enhanced price. Witness knew of the result of the trial before the Lord Chief Justice.

Mr. JAMES GRAY, secretary to the plaintiff Company, produced the books of the Company, and gave evidence as to their contents, after which

Sir F. LOCKWOOD, for the defence, said that his contention would be that in the negotiations which led up to the contract of February 26, 1892, the interests of the South Staffordshire Company were betrayed and the interests of the plaintiff Company ignored. The view he presented to the Court was that so far as the plaintiff and the defendant companies were concerned the beneficial nature of this contract to either of them was absolutely ignored, and the only object was to capture the South Staffordshire Tramways Company and its advantageous concessions. In the negotiations for the contract between the parties the interests of the Tramways Company were not only betrayed by those who were representing it, but the interests of the plaintiff company were entrusted to one who knew perfectly well how the South Staffordshire Company was being treated. The position of the plaintiff Company, he took it, was this: so far as its directors were concerned they should have employed as their agent a person who was perfectly cognisant of the fraud which was being practised on the South Staffordshire Company, it might be they could not be held responsible in damages in respect of the fraud of their agent, but it was perfectly clear they could not avail themselves of any contract entered into under such circumstances. He admitted that he had to satisfy the Court that Mr. Ebbsmith in this matter was the accredited agent of the plaintiff Company. It had been clearly proved in another action that Ebbsmith had manœuvred the affair of the South Staffordshire Company for his own benefit, and this had gone on for some years, when Ebbsmith conceived the idea that it would be a good thing to obtain powers to use electricity as a motive power for the tramways. The necessary Parliamentary sanction was accordingly obtained. The assistance of Jabez Balfour was then sought by Ebbsmith, and they, between them, promoted the Electric Construction Company, and the first matter to come before the Board was the contract now in question. He therefore submitted that if he fixed Mr. Ebbsmith as the agent of the plaintiff Company he would be entitled to read the pleadings and the judgment in the action before the Lord Chief Justice referred to.

His LORDSHIP said he would admit that evidence *de bene esse*.

Sir F. LOCKWOOD submitted that if he established that the contract was oppressive, and that the Tramways Company could not survive under it, then the plaintiff Company must fail, and he was entitled to rescission of the contract.

The judgment and evidence in the former trial was then put in and read.

Evidence was then called for the defence.

Mr. THOS. PARKER said he was an unwilling witness. He was works director of the plaintiff corporation. His opinion was that the cost of the construction of the works would be £24,000. The tramway lines had been constructed by himself and his staff, and he had frequently inspected the lines. Before the execution of the contract he prepared and sent a specification to Mr. Ebbsmith. He was introduced to Mr. Jabez Balfour in London, but not by Mr. Ebbsmith. His opinion was that if the South Staffordshire Company had to pay 9d. per mile for the working of the Company it would not survive. He expressed that opinion to Mr. Ebbsmith and other Directors of the Company. After he left the plaintiff Company he started a company called Thomas Parker (Limited). The plaintiff Company offered to pay him £1,000 a year to remain with them, and also to allow him to carry on a private company. Considering he was a servant of the Board, he spoke as strongly as he could against the contract. At the time the contract was carried out he was works director. He did not consider the cost price as taken from the books was accurately given, his impression being that the cost was at least one-third more. In January, 1894, several of the directors desired him to continue as works manager, and when he refused he was requested to remain in the employ of the plaintiff Company as consulting engineer at a salary of £1,000 a year. He gave notice to the Company on February 17, 1894, that he should leave their employ at the termination of his agreement on May 30, 1894, and on April 9th he wrote asking that the employment might cease forthwith.

Mr. EVE said this evidence rendered it necessary that he should call the directors of the Company, as his information was that witness had never given any intimation to leave until he wrote the letter of February 14, 1894, and that, instead of requesting him to continue in the service of the Company, it was desired that his engagement should terminate before the end of the agreement.

Sir F. LOCKWOOD said he should oppose any application to call witnesses after the plaintiffs had closed their case, particularly as he put to Mr. Courtenay the question whether it was not the fact that Mr. Parker informed him of his belief that the contract was of such an onerous nature that it would be impossible for the defendant Company to survive it. The allegation against Mr. Parker was that he was a dismissed servant of the Company, and was consequently prejudiced against the Company. It was not until now that he learned of the letter giving notice of the termination of Parker's agreement which was sent to the plaintiff Company on February 14th.

Mr. Justice ROMER said that he would consider the application.

Further evidence was then given, and the hearing was adjourned till to-day (Friday).

## Central London Railway Company.

In the London Sheriff's Court on Saturday an action was heard in which the Kensington Woodhouse Park Syndicate endeavoured to obtain from the Central London Railway Company £28,000 as compensation for the compulsory acquisition of their estate at Shepherd's Bush. This is the action which has thrown such strange light upon the financial results of the exhibitions held of late years at Earl's Court, &c. The presentation of these statistics proved effective against the excessive claim put forward in this action, and after a lengthy hearing the jury awarded £4,950 as full compensation.

## Von Buch v. Grant.

In the London Sheriff's Court on Friday last Mr. Carl von Buch, described as "electrical engineer and company promoter," sued Mr. C. N. Grant for slander. Plaintiff's counsel stated that the defendant described his client to a Mr. J. C. Mackenzie as "a wrong 'un," in league with a gang of thieves, and one of the worst men in the City of London. Although the plaintiff bore a German name he was in reality an Englishman. He was a graduate of Oxford, and carried on business as an electrical engineer. Even if the jury awarded £10,000 damages the plaintiff would not be able to sell his verdict for 6d., as the defendant was an undischarged bankrupt, and quite recently he had taken his passage to Australia. After hearing the evidence of the plaintiff and Mr. Mackenzie the jury awarded £100 damages.

## London Electric Supply Corporation (Limited) v. Prentice.

On Wednesday, at the Westminster County Court, a claim was made by the plaintiff Corporation for £15 for breach of contract. A contract was signed by defendant for the plaintiffs to supply the electric light at 60, Park-street, W. After signing, defendant said he did so under a misapprehension, and the contract was not carried out. Plaintiffs now sued for £10 as loss of profit, £1 for three plans, and £4 for men's time.

Mr. PARKER, a clerk, said defendant, after signing the contract, said he did not want plaintiff Corporation but the Westminster Company to carry out the work. The plaintiff had to send plans to the County Council before they brought their mains into the street. They went on with the work after getting notice from defendant that he had signed the contract under a misapprehension. The Westminster Company were supplying the light to the former tenant of the house. Plaintiff Corporation had an agreement with the Westminster Company "not to try and steal each other's business."

The JUDGE: Why do you fight this? You all seem at cross purposes. You have an understanding with the Westminster Company not to take their streets, or whatever it is. If you recover anything it will not be more than £10. I should think you might settle it during lunch time.

The action was, however, not settled, and for the defence it was urged that plaintiffs' canvasser brought the contract and defendant signed it under the belief that he was signing a contract with the Westminster Company to re-connect, and that Company had now done the work.

The Judge was of opinion the Westminster Company had acted as fairly as any company could, judging from correspondence and the evidence. Judgment would be for the defendant with costs. Defendant signed a contract under a misapprehension for the plaintiffs to put on the light. They had not done so, but the Westminster Company had.

### Clarke v. Julius Sax and Co. (Limited).

This case came before the Court of Appeal on Friday last, being the appeal of Messrs. Julius Sax and Co. (Limited) from a decision of Mr. Justice North in the Chancery Division, refusing to rectify the register of designs by striking off design No. 206,807, registered by John C. Clarke, on the ground that it was not novel, and that similar designs had been used before, the design consisting of a lamp used for an electric lamp to light shop windows. The case was reported in *The Electrician* of Feb. 14th last.

Mr. VERNON SMITH, Q.C., for the appellants, said an action was originally brought by Mr. Clarke against Julius Sax and Co. (Limited) to restrain them from infringing on his design, upon which Messrs. Julius Sax and Co. introduced their cross-notice of motion to rectify the register by striking it off. Mr. Justice North dismissed both motions, holding that the design was one which was entitled to be registered, and that Messrs. Julius Sax and Co. had not infringed it. Only one order was drawn up, and notice of appeal was served before that was done. The only matter to consider now was whether the design in question ought to remain on the register, the contention of the appellants being that the design was not within Section 47 of the Act of 1883.

At the conclusion of the arguments of counsel their Lordships reserved judgment.

### Chadwick v. British Insulated Wire Company (Limited).

At the St. Helens County Court, on Wednesday last, Samuel Tate Chadwick and his wife Barbara sued the British Insulated Wire Company for £50 compensation for injuries sustained by the female plaintiff through the alleged negligence of the defendants. For the plaintiffs it was stated that some time ago the defendants were laying electric light mains in St. Helens, and Mrs. Chadwick fell into an excavation and sustained injuries, both knees being hurt and bruised; in addition, she had suffered a severe shock to the system, and had incurred expenses for medical attendance, &c. On the case being called it was announced that the matter had been settled, the defendants paying £40 in settlement.

## TRADE NOTES AND NOTICES.

*[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]*

TENDERS INVITED.—The vestry of Hammersmith require tenders for (*a*) supplying and laying high-pressure and low-pressure cables and pipes, (*b*) supplying and erecting arc lamps and lamp posts, (*c*) supplying and erecting transformers and sub-station equipment, (*d*) supplying and erecting a 5-ton overhead travelling crane. Specifications, &c., can be obtained of Mr. A. H. Preece, 39, Victoria-street, London, S.W., and tenders must be delivered at the vestry offices, 57, Fulham Palace-road, Hammersmith, by noon of Wednesday, May 27th. Mr. W. P. Cockburn is vestry clerk. Some further information is given in our advertisement columns.

——— The Bray Town Council invite tenders for the supply and delivery of a 75-kilowatt steam alternator, a 200 H.P. Lancashire boiler, a 100 H.P. vertical high-speed engine, a fuel economiser, feed pump, &c. Tenders must be sent in to the Town Clerk (Mr. P. MacDonnell, Town Hall, Bray, by the 18th inst. Some further information will be found in our advertisement columns.

——— The Electric Light Committee of the County Borough of Oldham invite tenders for the supply of one 360 H.P. steam engine and dynamo. Tenders by May 12th.

——— The Public Lighting Improvement Committee of St. Helier, Jersey, invite communications from persons wishing to establish a lighting station in that town for the supply of electric, gas, or other forms of light for both public and private purposes. Communications should be sent to Mr. P. Baudains, Ecr. Constable, Town Hall, St. Helier, Jersey.

——— Tenders are required for the provision and fixing of electric bells, telephones, fire alarms, &c., at the Brook Fever Hospital, Shooter's Hill, S.E., for the Metropolitan Asylums Board. Tenders by 2 p.m. on Wednesday, May 6th.

——— The Electric Lighting Committee of the Coventry Corporation invite tenders for the supply and erection of (*a*) boilers and fittings, mechanical stokers and economiser, feed pump, &c.; (*b*) steam engine, alternator, oil filter, fittings, &c., steam, exhaust, feed, blow-off, and sundry pipes, valves, &c. Tenders to the Town Clerk, St. Mary's Hall, Coventry, by May 12th.

——— The Council of the City of Wakefield invite tenders for the construction and erection of an electricity generating station. Tenders to the Town Clerk, Town Hall, Wakefield, by the 13th inst.

——— The General Direction of Roumanian Posts and Telegraphs require tenders for the supply of 40 tons of galvanised iron wire and 10 tons of galvanised steel wire. Tenders to the Direction at Bucharest, by the 12th inst.

——— The Sunderland Corporation require tenders for the extension of their electric supply station and also for an iron roof. Tenders by the 6th inst.

TENDERS INVITED.—The Telegraph Department of the South African Republic invite tenders for the supply of 10,000 insulators with supports. Specifications, &c., may be obtained from Messrs. Belinfante Bros., Paveljoensgracht, The Hague, Holland. Tenders to the Consul-General, 8, Doelenstraat, Amsterdam, by the 15th inst.

TENDERS ACCEPTED.—The Cardiff Town Council have received the following tenders for the supply of additional plant at their electricity generating station :—

*Engines and Alternators.*

| | Type of engine. | Type of alternator. | K.W. | Speed. | Price. |
|---|---|---|---|---|---|
| S. Z. de Ferranti (Ltd.) (*Accepted*) | Ferranti's | Flywheel | 300 | 200 | £3,250 |
| Ditto | Belliss | Do. | 350 | 350 | 3,500 |
| Electric Construction Co. | Peache | E.C.C. | 250 | 350 | 2,493 |
| Ditto | Pollitt and Wigzell | Do. | 300 | 127 | 2,970 |
| Ditto | Belliss | Do. | 300 | 300 | 3,407 |
| Brush Company | Raworth | Mordey | 300 | 266 | 2,668 |
| Crompton and Co. | Peache | Crompton Brunton | 300 | ... | 2,770 |
| Ditto | Willans | Crompton Brunton | 300 | ... | 3,015 |
| Ditto | Belliss | Do. | 300 | ... | 3,051 |
| Johnson and Phillips | Do. | J. and P. | 300 | 300 | 3,350 |
| Siemens Bros. and Co. | Do. | Siemens | 300 | 300 | 3,560 |
| Ditto | Wil'ans | Do. | 300 | 267 | 3,740 |
| Easton, Anderson and Goolden | Corliss | Patent | 300 | 120 | 4,100 |

*Boilers.*

| | | | | |
|---|---|---|---|---|
| E. Danks (*accepted*) | Dry back marine | £767 | 10 | 0 |
| J. Thompson | Economic | 890 | 0 | 0 |
| Fraser and Sons | Dry back marine | 974 | 0 | 0 |
| G. Sinclair | Do. | 990 | 0 | 0 |
| Davey, Paxman and Co. | Economic | 998 | 0 | 0 |
| Crompton and Co. | Do. | 1,023 | 0 | 0 |
| Tinkers (Limited) | Dry back marine | 1,060 | 0 | 0 |
| Fleming and Ferguson | Clyde water tube patent | 1,079 | 0 | 0 |
| Ditto | Do. | 1,095 | 0 | 0 |
| Lindsay, Burnett and Co. | Dry back marine | 1,100 | 0 | 0 |
| Hawksley, Wild and Co. | Do. | 1,110 | 0 | 0 |
| Babcock and Wilcox (Ltd.) | Water tube | 1,100 | 0 | 0 |
| Abbott and Co. | Dry back marine | 1,150 | 0 | 0 |
| Electric Construction Co. | Do. | 1,155 | 0 | 0 |
| R. Hornsby and Co. | Do. | 1,400 | 0 | 0 |
| John Brown and Co. | Scotch marine with patent draught, &c. | 3,700 | 0 | 0 |

——— For the wiring of the Northern Polytechnic Institute seven tenders were received, and the lowest, that of Messrs. Russell and Lennard (£219) has been accepted. The other tenders ranged from £245 to £1,027.

WESTINGHOUSE ENGINES FOR SALE.—An important list of engines for sale by the Metropolitan Electric Supply Company will be found in our advertisement columns, including engines of 320 I.H.P., 250 I.H.P., and 85 I.H.P., all fitted with variable expansion gear controlled by flywheel governors.

APPOINTMENTS VACANT.—The Shoreditch Vestry invite applications for the post of resident electrical engineer to take charge (under the superintendence of the Vestry's consulting electrical engineers) of the laying of mains, the erection of plant at the electricity station, &c., for a minimum period of four months at a salary of £4 per week. Applications must be sent in to Dr. H. Manstield Robinson, The Town Hall, Old-street, London, E.C., before 4 p.m of the 11th inst. Some further particulars are given in our advertisement columns.

APPOINTMENT.—The Hampstead Vestry have appointed Mr. Harold Morton to the post of assistant electrical engineer at the Vestry's electricity works, in place of Mr. C. O. Bastian resigned.

——— Mr. J. Davies Williams, Town Clerk of Southport, informs us that Mr. Charles Davis Taite, who has been engaged as an assistant at the Southport Electricity Station, has been appointed borough electrical engineer, in place of Mr. Arthur Ellis, who has been selected to fill the Bolton vacancy.

DISSOLUTION OF PARTNERSHIP.—Messrs. Alfred, Stephen Francis and Francis Pegler, india-rubber manufacturers, hitherto trading under the style of the Northern Rubber Company, at East Retford, Nottingham, have dissolved partnership. Mr. A. Pegler retires.

BUSINESS CHANGES.—Messrs. Charles Jennings and Co. have become successors to the firm of George Schultz and Co., engineers, steel and iron merchants, of 90, Cannon-street, London, E.C.

Digitized by Google

BANKRUPTCIES.—Claims against the estate of Philip C. Pope, electrical engineer, Hapton, near Burnley, must be sent in to the Official Receiver (Mr. T. Edelston), County Court, Preston, by May 6th.

——— A first and final dividend of 7s. 6d. is payable in the estate of George I. Reakes, electrical engineer, lately trading as G. Reakes and Co., Cherry Orchard, Shrewsbury, at the Official Receiver's, Shrewsbury.

——— The liabilities in the recent failure of W. Northcote and Co., electricians, of New Cross-road, London, are returned at £379. 10s. 10d., assets at £25. 5s.

——— At the London Bankruptcy Court on Tuesday an application was made by G. F. Rogers, electrical engineer, for his discharge. The receiving order was made in March, 1895, and from the Official Receiver's report it appeared that the bankrupt was a director of various companies, and had signed a number of bills. The debtor attributed his failure to liability on accommodation bills, loss on trading and investments, law costs, bad debts and depreciation of securities. Liabilities were returned at £19,800. 14s. 3d., and the assets have realised £496. 13s. 3d. Among other offences it was alleged against the applicant that the assets were not equal to 10s. in the £, and that he had been guilty of rash and hazardous speculation and extravagance in living. In the end his Honour suspended the discharge for three years.

EXPORTS OF ELECTRICAL APPARATUS AND MATERIAL.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from April 22nd to 28th, with the ports of destination :—

*Australasia*—Adelaide, £3,220; Melbourne, £22; Sydney, £421; Wellington, £52. *Belgium*—Antwerp, £75. *Hong Kong*, £10; *China*—Shanghai, £110. *France*—Brest, £1,200. *Germany*—Cologne, £75. *Gibraltar*, £36. *Holland*—Amsterdam, £110. *India*—Bombay, £101; Calcutta, £380. *Japan*—Yokohama, £715. *Malta*, £692. *Panama*—Santos, £89. *Russia*—Revel, £31; St. Petersburg, £563. *South Africa*—Cape Town, £123; Durban, £36; East London, £50; Port Elizabeth, £15. *Spain*—Barcelona, £7. *Straits Settlements*—Singapore, £28. *Sweden*—Stockholm, £120. *United States*—Baltimore, £13 (carbon diaphragms).

I. E. S. ACCUMULATORS.—We have received a new catalogue, issued by the I. E. S. Accumulator Company, of Palace Chambers, Bridge street, London, S.W., which gives useful details of the manufacture of these cells. Tabulated statements show the working rates, approximate capacity, dimensions, &c., of the various types of I. E. S. cells, which include batteries for traction and lighting purposes, and one cell called the "Central 'D' Type Station" (a description which is not particularly clear). One of the illustrations shows the I. E. S. battery for omnibus and tramcar lighting, reading lamps, &c. Some particulars are also given of the formation of I. E. S. accumulators.

ART FITTINGS.—A handsome catalogue of electric light fittings, illustrated by Mr. Holland Tringham, is issued by Messrs. F. and C. Osler, of Oxford-street, London, W. A large variety of pendants (fixed and sliding), ceiling lights, brackets, standard and table lamps, figure lamps, French bronzes, and an excellent assortment of shades for electric lamps and ornamental sundries are included in the catalogue. As might be expected, many of the designs possess high merit, and architects and contractors engaged in artistic electric light work can be safely recommended to consult the catalogue of this firm, which stands in the first rank in this particular department of the industry.

ELECTRICAL ADVERTISEMENTS.—On the opening of the exhibition at Earl's Court a novel form of advertisement is likely to be conspicuous. This is a series of luminous words formed of incandescent electric lamps, the letters of the words being 300ft. from the ground, and each 40ft. in height, and covering in all an area of about 10,000 sq. ft. From tests which have been made, on a clear night the illuminated letters would, it is stated, be visible for from six to eight miles, but whether legible at anything like so great a distance remains to be seen.

---

BATTERSEA (LONDON).—The result of the competition for the best method of dealing with a public supply of electricity in Battersea is announced. In September last the Vestry invited competitive schemes for the lighting of the parish by electricity and for the utilization of the dust destructor in connection therewith. Instructions were prepared and premiums of £50, £30, and £15 respectively were offered for the best three schemes submitted, it being stipulated that the schemes finally selected should become the absolute property of the Vestry, and the premium of the successful competitor in the event of his scheme being carried out, to merge into and form part of the commission or remuneration for the supply of the necessary detailed plans, specifications, &c., and for the general superintendence of the execution of the works. The schemes were, as usual in such cases, sent in anonymously, accompanied only by a sealed envelope containing the name and address of the competitor. The instructions were issued to 28 applicants, and 21 sets of schemes were submitted by December 12th. The Electric Lighting Committee then appointed Mr. Robert Hammond to advise them and to report on the schemes submitted. His report was considered by the Committee, and in accordance with his recommendations the premium of £50 has been allotted to the scheme prepared by Mr. R. A. Dawbarn on behalf of the Brush Electrical Engineering Company (Limited); the £30 premium to Mr. W. Best; and the £15 premium to Mr. J. Hardie McLean, of Oxford. The Committee have now given instructions for a scheme to be prepared for dealing with the electric lighting of the parish, which the Vestry will discuss at an early date. The electric lighting of the Town Hall is to be at once proceeded with, and Mr. Hammond has been appointed as the consulting engineer to carry out the work. It is estimated that the work will cost about £3,000. The generating plant for the Town Hall lighting will be erected on the vacant land at the rear of the present building. Application is to be made to the London County Council for a loan of £3,000.

BELFAST.—The petition presented by the Corporation against the Belfast Street Tramways Company's Bill has been withdrawn. The Company seek powers to construct new tramways and to introduce electric traction throughout the entire system. There is now no opposition to the Bill.

BLACKPOOL.—A Local Government Board inquiry was held on Tuesday last at Blackpool into the application of the Town Council for permission to borrow £30,000 for making extensions to their electric lighting system. Particulars of the application were given by the Town Clerk (Mr. T. Loftos). The electrical engineer (Mr. J. Hesketh) stated that further extensions of the works were urgently needed; at the present time the demand for current was so great that they could not supply all those who were willing to take it, and unless new plant were put down for the summer season the Electricity Committee would not be able to fulfil its obligations. A Mr. Sansome put various questions to the engineer with a view to show that orders for the new plant had already been given out, and that the work was well in hand, though without the Local Government Board's consent. Mr. Sansome made various other statements of a more or less irrelevant character, but finished up by supporting the extension of the works. There was no other opposition, and the inquiry terminated.

BOLTON.—This week a deputation from the Streets and Electricity Committees paid visits to Bristol and Walsall for the purpose of inspecting the electric tramways in these towns. It is anticipated that the deputation will recommend the adoption of the overhead side trolley system. It is proposed to start with the Daubhill route (about 2½ miles in length) which will afford a good test of the system as there is a steep gradient. The estimated cost of this section is £10,000. The total length of tramway rails owned by the Corporation is over 17½ miles.

BRAY.—The Town Commissioners held a special meeting on Monday for the purpose of considering the proposals of the British Electric Traction (Pioneer) Company to construct electric tramways in the town. After considerable discussion it was decided to adjourn the further consideration of the matter for six months.

COMMISSION OF SEWERS (LONDON).—At the last meeting of the Commissioners the Streets Committee presented their report on the recent application of the National Telephone Company for permission to lay their telephone wires underground. The report concluded as follows :—"That as the Company was not prepared to make any concession for the public benefit for the easements in question, they were unable to recommend compliance with the application." The Committee's recommendation was unanimously agreed to.

DONGOLA CAMPAIGN.—Lieut. Manifold, R.E., has succeeded in laying the telegraph to Akasheh by the river route. The greatest distance accomplished in one day was 15 miles. No. 8 wire was employed. Telephonic connection has also been established. There is said to be some difficulty in finding skilled telegraph operators.

ELECTRIC LIGHT AND NIGHT TARGET PRACTICE.—It is stated that an electrical plant has been laid down at Lydd, near the Camp, for the purpose of working the search light to be used during heavy-gun firing practice at various objects during the night.

GARSTON (LANCS.).—Major Philip Cardew, R.E., held a Board of Trade inquiry on Tuesday last into the application of the Liverpool District Lighting Company for a Provisional Order for the districts of Garston and Much Woolton. Opposition was offered to the scheme by the Garston District Council.

GLASGOW.—This week a deputation from the Town Council are paying a visit to Hamburg for the purpose of making a detailed examination of the system of electric traction employed on the tramways of that city. The deputation are also to visit Bristol and Coventry. Until a report is presented the consideration of Messrs. Crawford and Young's report, a short abstract of which was given in our last issue, is postponed.

Digitized by Google

GRIMSBY.—The Grimsby Council Provisional Order expires in July next, and at a meeting held on Friday last, Mr. Alward made some practical suggestions as to the measures which ought to be taken for the immediate establishment of electricity supply works if the Order is to be retained. A motion was, however, made to apply for an extension of time, and the Town Clerk pointed out that if the Council waited until the close of the present Session of Parliament, and applied in November for an extension, there was no doubt this would circumvent any private company stepping in before them. In the meantime particulars are to be obtained of electric lighting matters from other towns.

HAMPSTEAD (LONDON).—The Vestry have approved the plans of the proposed additional buildings at the electricity supply station, and tenders are to be invited. Various small extensions of the electric light mains are also authorised at an estimated cost of £570, and testing instruments, stores, &c., at a cost of £122. 16s. The total number of applications to March 31st was 324, and 305 customers, representing 22,945 8 c.p. lamps, have been connected, an increase of over 3,500 8 c.p. lamps for the quarter. The works cost of the station for this period was £1,231. 9s., or 2·29d. per unit.

HOTEL LIGHTING.—The Great North of Scotland Railway Company have decided to introduce the electric light into the Palace Hotel at Aberdeen, and are negotiating with the Electric Lighting Committee for the supply of current from the Corporation mains.

HULL.—The Town Council are much exercised over the question of the system of traction to be adopted on the local tramways, and have now instructed the borough engineer to prepare a report on the various systems in use.

KINGSTON-ON-THAMES.—On the recommendation of the Electric Lighting Committee the Town Council have decided to lay a cable to the waterside for the purpose of charging electric launches.

KINGSTOWN (DUBLIN).—The Board of Trade have approved the application of the Town Commissioners for an Electric Lighting Provisional Order. The Lighting Committee's recommendation that Mr. Manville be authorised to prepare a report on the electric lighting of the town at a fee of 50 guineas was approved —— During the past week a number of cars have been running on the Dublin Southern Tramways Company's line between Kingstown and Dalkey for testing purposes. The line is to be shortly opened for traffic.

LAMBETH.—There was another full-dress debate on the electric lighting question at the last meeting of the Vestry. Various amendments were considered and numerous eloquent and persuasive speeches were delivered in support thereof, one member objecting to the Vestry undertaking a lighting scheme on "moral, social, financial and philosophical grounds." We were always under the impression that light was one of the most potent factors in the moral and social well-being of a district.

LEEDS.—*Daily Tenders and Contracts* states that notice has been given on behalf of the Leeds City Council of the intention to bring forward a motion to suspend the standing order which prohibits a Parliamentary Committee from giving power to the Corporation to work the local tramways. This course has been rendered necessary in consequence of the Government having adopted the principle in their Light Railways Bill of Local Authorities working tramways.

LIMERICK.—It having been suggested that the Corporation might be able to obtain sufficient water power from the river Shannon for lighting the town electrically, the consulting electrical engineer (Prof. A. B. W. Kennedy) has the matter under consideration.

MUSIC HALL LIGHTING.—The new Empire Music Hall, Cardiff, is to be lighted electrically.

KIDDERMINSTER.—Owing to the serious opposition with which the Bill for the construction of an electrical tramway from Kidderminster to Stourport was threatened, it was thought that the promoters would be compelled to abandon their scheme. It is now stated that the opposition has been withdrawn, except to minor features of the Bill. There is therefore every prospect that the Bill will be reported to the House at an early date, and that the work of construction will be started without delay.

MAIDSTONE.—At the last meeting of the District Council a long discussion arose on the proposal to transfer the Maidstone Provisional Order to Mr. Thomas King. Several members objected to the transfer, and ultimately it was agreed to let the matter stand over for twelve months.

MIDDLESBOROUGH.—Some time ago Mr. R. Hammond presented a report on the electric lighting question in which the Electric Lighting Committee were recommended to establish an electricity station at a cost of £10,000. After consideration of the report the Committee have decided not to proceed with the matter.

MILL LIGHTING.—The Moss Field Mills, Bolton, are being fitted throughout for the electric light by Messrs. W. Banks and Co. (Limited), Bolton.

PETERBOROUGH.—Some time ago the Town Council decided to borrow £20,000 for the purpose of establishing electricity supply works, but at the last meeting of the Council an attempt was made to rescind this resolution. Mr. Batten moved "that in view of the information acquired by the Council since January last it is undesirable to proceed with the application for the loan." In support of his motion Mr. Batten said that up to the present only 51 municipal bodies had established electricity works, while there were 50 private companies, and he contended this proved that it was not advisable for the Council to proceed with their scheme. Brighton, singular to say, was cited in support of the motion as a Town Council which had bought out the rights of a private company with a capital of £35,000 for £5,000. After a long and heated discussion the motion was rejected by 12 votes to 11.

PORTSMOUTH.—At the last meeting of the Electric Lighting Committee it was decided to increase the salary of the electrical engineer and superintendent of the Corporation electricity supply works to £275 per annum. Mr Price's initial salary was £200, but some time ago this was raised to £240 per annum. Other advances to the engineering staff were approved.

SHANGHAI.—The Municipality have had before them a proposal to grant to a syndicate represented by Messrs. L. S. J. Hunt and J. R. Morse, the right to construct a system of electric tramways. The scheme provided for the payment to the Municipality of 1 per cent. of the gross receipts from the tramways for the first five years, 1½ per cent. for the second five years, and an additional ½ per cent. for every succeeding five years until the maximum of 4 per cent. was reached. It was proposed that a local directorate should be formed and the public be invited to subscribe the necessary capital. After 25 years the Council were to have the option of purchasing the entire system on a valuation based upon its earning capacity. Serious opposition was offered to the scheme by the Council, and representations were made on behalf of the Imperial Chinese Telegraph Administration, the Eastern Extension and Great Northern Telegraph Companies, and the China and Japan Telephone Company, pointing out the serious effect of the heavy currents used in electric traction work upon the weaker currents employed for working the telegraphs and telephones, and suggesting that if the concession were granted it would be necessary to frame a set of rules safeguarding the interests of the telegraphs and telephones. The discussion upon the scheme at the ratepayers' meeting was worthy of the occasion, several speakers showing themselves fully acquainted with the views of leading experts on electric traction matters. In support of the introduction of electric tramways one speaker expressed his intention of approving the suggestion, even though the interests of Shanghai were temporarily affected. They were constantly asking the Chinaman to adopt western notions—to introduce railways, waterworks, and modern systems of lighting—and now that the opportunity was before them for introducing up-to-date electric traction in the city he, for one, welcomed the proposal. Most of the speakers agreed that it would be necessary, before introducing so great a novelty into the narrow streets of Shanghai, that the greatest care should be taken to safeguard the interests of the telegraphs and telephones, although one or two supporters of the traction scheme displayed a disposition to ignore these rights. After a discussion lasting some hours, the proposal to grant the concession was lost, the Council's opposition proving its death knell.

SOUTHAMPTON.—Mr. J. G. W. Aldridge, the electrical engineer to the Harbour Board, has suggested certain alterations to the new electric cranes on the town quay by which their lifting weight will be increased to three tons in place of 30cwt. at an additional cost of £100. The proposal has been adopted.——The Electric Lighting Committee of the Town Council have appointed Mr. E. Manville their consulting electrical engineer. The members of the Committee this week paid a visit to Portsmouth for the purpose of inspecting the electricity works of that town.

SOUTHPORT.—A Local Government Board inquiry was held on Friday into the application of the Town Council to borrow £4,000 for additions to the electric light mains, &c. The Town Clerk (Mr. J. Davies) gave particulars of the expenditure the Council had already incurred in connection with the electricity supply scheme, and stated there was a steady increase in the demand for current. The electrical engineer (Mr. A. Ellis) supplied technical details. There was no opposition.

STORES LIGHTING.—The Haslingden Industrial Co-operative Society have decided to introduce the electric light into four of their shops at a cost of £470.

WESTMINSTER (LONDON).—The Vestry have decided to make some alterations to their electric light installation at the Public Baths at a cost of between £250 and £300. Tenders for the work have been invited from Messrs. Crompton and Co., Drake and Gorham, Nalder and Harrison Syndicate, the Electrical Installation Company and Mr. T. J. Rorke.

WORCESTER.—The action brought by Messrs. Quarrell and White against the City Council for damage alleged to have been caused by the Electricity Committee in the erection of the Powick electricity works has been settled, a compromise having been effected by payment of £50 as compensation in addition to costs.

# COMPANIES' MEETINGS AND REPORTS.

## Eastern Extension, Australasia and China Telegraph Company (Limited).

The forty-fifth ordinary general meeting of this Company was held at Winchester House, London, E.C., on Wednesday, under the presidency of the Marquis of Tweeddale.

The SECRETARY (Mr. F. E. Hesse) read the notice calling the meeting and the minutes of the last meeting, which were signed as correct. The report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, before referring to the proceedings of the past half-year, I desire to express the deep regret of myself and my colleagues, as well as, I believe, of every shareholder, present and absent, at our being deprived of the presence of our able and esteemed chairman, Sir John Pender, through severe indisposition. Sir John Pender has been chairman of this Company ever since it was founded in 1873. I believe that he has presided at every half-yearly meeting since that date. He gave the Company his unremitting attention, and it is only fair to say that it is due in great measure, if not entirely, to his foresight, energy, and administrative ability that we owe the success which this Company has achieved. No more conspicuous evidence of this could be found than is contained in the report which I am going to ask you to adopt to-day. The gross revenue for the half-year under review has amounted to £311,582, against £261,322 for the corresponding period of 1894, or an increase of £50,260. As mentioned in the printed report, this increase is mainly due to the exceptionally heavy traffic exchanged with Western Australia in connection with the gold mining industry that has so largely developed in that colony. This industry may prove lasting, or it may only be a temporary industry. All gold mining, however, being more or less speculative, we must not reckon upon a continuance of these abnormal conditions. The working expenses for the half-year have amounted to £84,044, against £89,740 for the corresponding period of 1894, or a decrease of £5,696, due to the cost of cable repairs having been much lighter during the past half-year than during the same period of 1894. As this is the close of the financial year, it will interest you if I compare the receipts and expenses of the whole year with those of 1894. The gross receipts for 1895 amounted to £575,722—the largest revenue the Company has ever earned—against £509,003 for 1894, or an increase for the year of £66,719. The working expenses for the same period show an increase of £9,263, but this is accounted for by the cable repairs being unusually heavy during the first half of 1895, whilst several exceptional items, such as repairs and additions to station buildings and furniture, also came into last year's accounts. It will be seen from the printed report and accounts that the Fire Insurance Fund has been credited with £20,000 from the revenue account. This fund was started some two years ago owing to the premiums charged on the Company's property abroad being considered excessive for the risks involved. The Company thereupon decided to underwrite three-fourths of the risk, and as the property insured is valued at about £125,000, the fund was obviously inadequate without a considerable addition being made to it. It now stands with this addition at £26,159. It will be necessary to make further additions before this fund can be considered in a thoroughly sound condition. The usual interim dividends have been distributed during the past year, making, with the dividend proposed to be paid to-morrow, a total payment of 5 per cent. for the year 1895. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the past year. The balance of £129,329 has been carried to the general reserve fund, which, after debiting the fund with the balance of cost of the alternative Singapore-Hongkong cable, and the cable renewals effected during the half-year, now amounts to £561,546. This is a substantial figure, no doubt, but having regard to the great length of our cables over 18,000 nautical miles—we can hardly regard this sum as sufficiently large. It will be necessary therefore still to add to the reserve fund. The renewals I have referred to consisted of the insertion of 340 knots of cable in the New Zealand original section, which had given from time to time considerable trouble, and 109 knots in the Tasmanian original section. Further extensive renewals have still to be carried out at various parts of the system in order to effectually maintain its efficiency, and these will be done as opportunities occur. I am happy to say that at this moment all our cables are in good order. I believe this is almost the first time that such a statement has been possible at a half-yearly meeting. With so many cables, so many different seas, and exposed to so many different risks, it rarely happens that some one cable or other is not interrupted, but at this particular moment I am happy to say that in no instance is there any interruption to the transmission of messages by our cables. The report informs you that a further drawing of the Company's Five per Cent. Australian Subsidy Debentures (409 in number) took place on the 1st inst. for payment at par on July 1st next, when the debenture debt, which originally amounted to £640,000, will have been reduced to £168,600, and will shortly, of course, be extinguished. Whilst paying a handsome dividend, strengthening the Company's position by making judicious renewals, additions to reserve funds, and reductions of capital, your Directors have not been unmindful of the interests of the telegraphing public, and have accordingly decided to revise the local tariffs by placing them on a more uniform and satisfactory footing. Most of these tariffs were originally fixed without regard to any definite or uniform basis, and some of them have proved to be anomalous and even excessive. The change will come into operation on July 1st. The reductions are expected to result in a considerable loss of revenue at first, possibly not less than £40,000 per annum. This is a statement which in many companies would be received with alarm, but I think you may receive it with equanimity. It is quite true that it is a very large figure, but at the same time we look forward to recouping gradually the loss by the increase which is almost certain to take place in our traffic. I have also to tell you that an international telegraph conference, to which the Company is invited to send delegates, will be held in June next, when it is quite possible that further sacrifices to meet public requirements may be pressed on the Company. If this proves to be the case the demand which may be made will receive the fullest consideration from us, and it will be our desire to meet it as far as possible, as far as it is reasonable, and as far as it is compatible with the interests of the Company. You have no doubt heard from time to time of proposals to connect Canada with Australia by means of a cable across the Pacific Ocean touching British possessions only. As many of the statements put forward in support of these schemes appear to be wanting somewhat in precision, and even in accuracy, I am glad to be able to say that an Imperial Commission will be held very shortly when this important matter will be fully considered. I rejoice at this, because I think it will be the first occasion on which the subject will be discussed in a thoroughly practical and businesslike manner by people who are thoroughly acquainted with the whole subject. My own impression is that the difficulties, both physical and financial, of giving effect to the desire for what is called an "all-British cable" (that is, a cable from Canada to Australia touching on no other than British possessions), will be found far greater than is generally believed; but whether this is the case or not our duty is clear—that is, to do all in our power to protect the interests of the shareholders of this Company. Without going into any detail as to how we consider that may be best done, I hope you will accept my assurance that it will be done, and done in a manner best suited to attain that end. I think I have now touched on all important matters connected with the operations of the last half-year. Again, I must express my deep regret that we have not with us to-day our able Chairman. I cannot, I am afraid, hold out the hope of seeing him here again, but I do indulge the hope that he may be restored shortly to, at any rate, a better condition of health than he at present enjoys. The motion I have now to make is

*"That the report and accounts of the Directors now submitted be received and adopted, and that a dividend be now declared of 2s. 6d. per share, together with a bonus of 4s. per share, both free of income tax, payable on the 30th inst., making, with previous distributions, a total payment of 7 per cent. for the year 1895."*

Mr. F. A. BEVAN: I have great pleasure in seconding that.

The CHAIRMAN: Before I put the Resolution I will invite any remarks which may have to be made. No shareholder, however, rising to address the meeting he put the motion in the usual way, and it was carried unanimously. Continuing, he said: I have next to propose

*"That Mr. John Denison Pender, who now retires by rotation, be and is hereby re-elected a Director of this Company."*

Mr. C. W. EARLE: I second the motion with much pleasure.

The resolution was carried unanimously.

Mr. BEVAN: I now beg to propose a resolution which the Chairman cannot move, as it affects him. It is as follows:—

*"That the Most Hon. the Marquis of Tweeddale, who now retires by rotation, be and is hereby re-elected a Director of this Company."*

Sir. A. J. LEPPOC CAPPEL, K.C.I.E.: I have the pleasure of seconding that resolution.

The resolution was carried unanimously.

The CHAIRMAN: I beg to thank you for the honour you have done me.

Mr. JOHN NEWTON: I beg to propose "That Messrs. Deloitte, Dever, Griffiths and Co., and Messrs. Welton, Jones and Co., be and are hereby elected auditors for the ensuing year at a remuneration of £100 each." May I take the opportunity, in moving this resolution, to express to the Directors, I am sure on behalf of all the shareholders—our great regret at the absence of our respected chairman, and to assure Sir John Pender and his family of our sorrow in their great calamity. I think you held out some little hope that Sir John may live to take an interest in what is going on respecting our affairs, and I do trust that he may live to see the great prosperity which the Company has been brought to. We are told that this is the most successful and prosperous year the Company has ever passed through, and it is a source of great regret that Sir John Pender is not in a condition to be with us on such an occasion. We may hope with you that he may recover to take an interest in the progress of our Company and that he may live long in restored health with his family.

Mr. ANSELL seconded the motion, which was carried unanimously.

The CHAIRMAN: That constitutes the business of the meeting.

Mr. W. GRIFFITH: I think we ought to propose a vote of thanks to our able Directors for the way in which they have managed our business in the past half-year. While proposing this I may take the opportunity of expressing my acquiescence in the sympathetic remarks which have been made respecting Sir John Pender. I hope that the Marquis of Tweeddale will transmit this expression of feeling from the meeting, and that it may be some comfort to him and his family in their affliction. We all trust that he will soon be restored to health and to us again. I now beg to propose a vote of thanks to the Directors for their able and successful conduct of our business in the past six months.

Mr. ANSELL, I beg to second that

The resolution was carried unanimously.

The CHAIRMAN: On behalf of my colleagues and myself I beg to express my thanks for the kind manner in which you have received this vote. I hope the next time we meet I may be able to give you a better account of our chairman, although I am afraid it will not be a very good one even then.

The proceedings then terminated.

## Indo-European Telegraph Company (Limited).

The twenty-ninth ordinary general meeting of the members of this Company was held at Winchester House, London, E.C., on Wednesday, Mr. J. Herbert Tritton presiding.

The MANAGING DIRECTOR (Mr. W. Andrews) read the notice convening the meeting.

The CHAIRMAN said: Gentlemen, I beg to propose—

*"That the report and accounts now submitted be received and adopted, and that a dividend be and is hereby declared for the half-year ended December 31, 1895, of 17s. 6d. per share, making, with the interim already paid, 6 per cent., and a bonus of 20s. per share, both free of income tax, making in all 10 per cent. for the year."*

In submitting that motion to you there is very little to be said in reference to the transactions of the past year. The year has been a blank as far as unusual or exciting variations of occurrences are concerned. Perhaps you will agree with me in preferring the unexciting and quiet march of assured prosperity to the stirring but unproductive episodes that occasionally attend upon companies in exciting but altogether undesirable forms. We have, fortunately, to deal with a satisfactory revenue. Our receipts for 1895, as the report shows you, amounted to £123,734. 11s. 7d., and compare in a favourable manner with the revenue of the preceding year, which only reached £119,117. 18s. 3d., the increase on the year being £4,616. 13s. 4d. We owe this increase to the trans-Indian business, and we owe that again to the discoveries of gold in Australia and the consequent development of new forms of telegraphic communication, which, it must be remembered, is bound to increase and to grow with the prosperity and enlargement of trade consequent upon the gold discoveries and their influence upon the Australias. With respect to India, our trade is pretty much where it was; there is a slight increase, but the income derived from the traffic has not made up the lee-way that set in with the reduction of rates made in the year 1885. I am afraid we must face the fact that in an old-established trade improvements and additions made year by year in merchants' codes, by which an enormous number of words in plain language can already be sent for one code word, absorb, so to say, any growth in the number of words there might otherwise be. In fact, the code tariff per plain word over the wires with India takes rank amongst the lowest tariffs in the world, and for each 100 miles of line, is so very much below the charge made, for instance, by the Post Office for telegrams in this country, as to be beyond all reasonable comparison. This may seem a startling announcement, but it can be proved by figures in the knowledge and in the possession of this Company. Turning to the other side of the account our expenses in the year 1895, under all heads, were £67,820. 10s. 4d., exceeding by £2,981. 17s. 3d. those of 1894. They include, however, certain items written down in pursuance of the policy which you have already several times approved. After deducting these expenses, the interim dividend already paid, and the amount placed to reserve, the Directors are enabled to recommend the dividend and bonus announced in the report. There will be next June at Buda Pesth a conference of delegates from the states parties to the Telegraph Convention. At this conference, to which the companies are invited to send representatives, the rules and regulations and tariffs affecting national and international telegraphs will be discussed and settled.

Major-General G. B. TREMENHEERE, R.E., seconded the resolution, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. C. HOLLAND, the retiring Directors, Messrs. L. Delbrück and C. W. Earle were re-elected unanimously.

The auditors (Messrs. C. F. Kemp, Ford and Co.) having been also reappointed, a vote of thanks to the Chairman and the other Directors brought the proceedings to a close.

## Great Northern Telegraph Company.

The following abridged report of the general meeting, held at Copenhagen on April 25th, is issued:—

Mr. F. Zahle presided, and the Managing Director (Commodore E. Suenson, D.R.N.) gave an account of the working of the Company during the past year. He said that, with regard to the state of the cables, the year 1895 had been less favourable than the preceding one. In Europe nine cables had been interrupted 16 times, and in the Far East there had been 14 interruptions of six of the cables, without reckoning renewals and strengthenings of weak places. The cable steamer "H. C. Orsted" had been employed on active service for 157 days and the "Store Nordiske" for 229 days, 113 of which, however, were for the account of other administrations, including the Japanese Government. Amongst the work executed for the latter was a second connection between the Japanese Islands of Tsushima and Iki, the cable having been taken from their stock in China, and the value credited to the reserve fund. In Siberia the Wladiwostock line had not given all the satisfaction that could be desired, neither with regard to the condition of the line itself nor to the transmission of the traffic. The Russian Government has, however, sanctioned the outlay of considerable amounts for improvements, and the Imperial Telegraph Administration is actively engaged in the restoration of the line and the reorganisation of the service. The military and political events in the Far East, which during the latter half of 1894 created an extraordinary traffic on our eastern cables, might be said to have lasted during nearly the whole of 1895, although the war between China and Japan was practically ended in March, and peace finally concluded on April 17th last year. Japan had, however, to continue military operations on the Island of Formosa, the pacification and annexation of which was accomplished towards the end of the year. The missionary troubles and the insurrectionary movements in China, as well as the numerous political and financial negotiations between Europe and the far East were also responsible for the large traffic during the past year. Nearly the whole of this traffic had passed over their cables, as the competing Chinese lines had practically been closed owing to the war and to the refusal of the Chinese Administration to transmit code telegrams over their lines, and it was only in December last that the competition of the Chinese line (the Helampo route) with the cables was resumed, and it was taken up with the same animosity as in 1893-94, forcing them to reduce their rates in China to the same level as those of the Chinese. This resumption of the competition came on them as a surprise, as in order to avoid it they opened friendly negotiations with the Chinese Administration in March last. In these negotiations they went to the utmost possible limit of concessions, but the competition was resumed without any definite answer having been given to their proposals. In spite of this, and thanks to the extraordinary events already mentioned, and to the satisfactory traffic on the European system, the year 1895 had, nevertheless, been an exceptional one from a financial point of view. The net traffic receipts amounted to £370,700, or £55,935 more than in 1894, although the value of the dollar had not sensibly increased during the year. "Sundries" also came to an unusual figure, due to the extensive employment of the cable steamer "Store Nordiske" by other administrations, as already referred to. The Board of Directors have, therefore, decided to propose to make the final dividend 2s. 10d. per £10 share more than the preceding years, which would make a total dividend of £1, or 10 per cent. This proposal has been made by the Directors after considerable hesitation. It might have been more prudent to keep the whole of the exceptional surplus receipts in reserve, in order to place the Company in a better position to face the demands and claims which are sure to be made in the near future, although provisionally put off by extraordinary and unforeseen events. Their differences with China were sure to entail great sacrifices on their part, and in addition they must be prepared to meet demands for great reductions in their tariffs at the forthcoming International Telegraph Conference. Lastly, the efforts for completing the submarine telegraph system of the globe by the laying of cables in the Pacific had lately developed to such an extent that they might be called upon at any moment to take an active and costly part therein. With the view of strengthening their resources and their resisting power, the Amortisation Fund has been increased by adding an extraordinary amount to the same. Finally, in referring to the death of Col. V. Hoskier Commodore Suenson said the Company had suffered a great loss through his death. Col. Hoskier took a very active part in the organisation of their technical service in the early days of the Company, and supervised the manufacture and laying of several of their cables.

The report and balance sheet were then unanimously agreed to. The retiring Director (Mr. C. F. Tietgen) was re-elected, and Lieut.-Col. V. E. Tychsen was elected a Director in the place of the late Col. Hoskier.

## London Platino-Brazilian Telegraph Company (Limited).

The report of the Directors to be presented at the meeting to be held at the offices, Blomfield House, London Wall, E.C., to-day (Friday) states that to December 31st last the total earnings amounted to £21,564. 17s. 8d., against £20,674. 6s. 8d. in the previous year, and the working expenses to £8,051. 5s. 11d., against £7,895. 11s. 10d. Including the amount brought forward (£332. 19s. 2d.) the balance to credit of revenue was £13,846. 10s. 11d., from which has been deducted £6,000 for debenture interest and £411. 11s. 4d. for income tax. After placing £1,500 to reserve, £5,934. 19s. 7d. remains for distribution. The Directors recommend that a dividend at the rate of £1. 5s. per cent. per annum (2s. 6d. per share) be paid for the year, carrying forward £1,241. 9s. 7d., payable to-day.

The lines of the Company are in good working order.

Mr. W. S. Andrews and Mr. D. H. Goodsall offer themselves for re-election as Directors, as do the auditors, Messrs. Deloitte, Dever Griffiths and Co.

## Submarine Cables Trust.

The following report of the trustees will be presented to the annual meeting of certificate holders, to be held at the offices, 50, Old Broad-street, London, this day (Friday), at 2:45 p.m.:—

The accounts for the financial year to April 15th show that the revenue, including the balance of £224. 11s. 5d. brought forward, amounted to £22,538. 6s. 6d. During the past year the usual coupon payments have been met. The expenses of the Trust amounted to £1,099. 14s. 4d., and payments on account of the coupons to £21,131. 5s. (together £22,230. 19s. 4d.), leaving £307. 7s. 2d. to be carried forward. The investments of the Trust remain unchanged since last year.

## NEW COMPANIES, STATUTORY RETURNS, &c.

**BROTHERTON'S TUBE COMPANY (LIMITED).**—This Company has been registered, with a capital of £20,000 in £1 shares, to acquire the undertaking of the Excelsior Tube Works, Wolverhampton, and to carry on the same.

**LIVERPOOL METER COMPANY (LIMITED).**—This Company was registered on April 25th with a capital of £30,000, in £1 shares, to carry on the business of mechanical engineers, electricians, iron and brass founders, metal workers, metallurgists, and of manufacturers and dealers in all apparatus required for or capable of being used in connection with the production, generation, distribution, measurement and employment of electricity and gas.

**RANSOMES AND RAPIER (LIMITED).**—This Company has been registered with a capital of £100,000, in 1,500 Preferred shares and 8,500 Ordinary shares of £10 each, to acquire the business carried on at the Waterside Ironworks, Ipswich, under the style of Ransomes and Rapier.

Digitized by Google

and to carry on the business of mechanical and electrical engineers, and manufacturers of engines, cranes and other machinery, tool and boiler makers, machinists, &c.

**TELESCRIPTOR SYNDICATE (LIMITED).**—This Company was registered on April 22nd with a nominal capital of £40,000 in £1 shares, to acquire certain patents and inventions of Bernhard Hoffmann relating to telegraphic apparatus and to typewriting machines, and also to establish, work, control and regulate electric recording systems, and to carry on the business of a telescriptor, veloscriptor, telephone and telegraph company. The first subscribers, with one share each, are:—L. Epstein, electrical engineer, P. Hoffman, C. M. Owen, B. Hoffman, inventor, P. Holyoake, C. F. Jones and C. Scott.

**LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED).**—The annual return to March 13th has been filed. 50,000 shares have been subscribed for out of a capital of £300,000, in £5 shares, and the full amount has been called and paid.

**NATIONAL TELEPHONE COMPANY (LIMITED).**—The annual return to March 5th has been filed. The nominal capital is £4.000.000, divided into 15,000 First Preference shares of £10 each, 15,000 Second Preference shares of £10 each, 250,000 Third Preference of £5 and 490,000 Ordinary shares of £5 each. All the First and Second Preference, 19,234 Third Preference and 484,597 Ordinary have been taken up; 28,284 Third Preference and 44,413 Ordinary have been issued as fully paid. The full amount has been called and paid on the remainder.

**SCARBOROUGH ELECTRIC SUPPLY COMPANY (LIMITED).**—The annual return to April 2nd has been filed. The nominal capital is £50,000, in £10 shares: 3,434 shares have been subscribed for, and a call of £9 per share has been made.

**SHEFFIELD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).**—The annual return to April 6th has been filed. 8,625 shares have been taken up out of a capital of £98,000, in £7 shares, and 4,000 have been issued with £5 per share considered as paid. A call of £4 per share has been made on 4,625, and £2 per share on 4,000 shares.

## CITY NOTES.

**MEMORANDA.**—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 31⅛d. per oz. (April 30th). Consols (2¾ per cent.) 111⅛–111⅛ for money, 111⅛–111⅛ for account; 2½ per cent. 105—105½ (April 30th). Stock Exchange Settling Days: Consols, May 4th to May 6th; Stocks and Shares Continuation Day, May 12th; Ticket Day, May 13th; Pay Day, May 14th; Mining Share Carry-over Day, May 11th.

**AKTIENGESELLSCHAFT FUR FABRIKATION VON KOHLENSTIFTEN VORM F. HARDTMUTH AND CO.**—This is the title of a Company which has been formed at Vienna with a capital of 1,260,000 marks (about £63,000) to acquire the business of manufacturers of electric light carbons, hitherto carried on by Messrs. F. Hardtmuth and Co., at Plania, near Ratisbor Silesia), and at Vienna, and generally to carry on business as carbon manufacturers and dealers.

**AKTIENGESELLSCHAFT MIX AND GENEST (BERLIN).**—The annual meeting of the shareholders of this Company was held on the 22nd ult., when a dividend at the rate of 8 per cent. was declared. The Directors report a promising outlook for the current year.

**ALLGEMEINE ELEKTRICITATS GESELLSCHAFT (BERLIN).**—It is stated that the Directors intend to increase the capital of this Company by M.3,000,000, in order to provide means for the further expansion of the business, and to erect cable works, a scheme for the establishment of which is at present being elaborated.

**CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).**—The traffic returns of this Company for the week ended April 26th were £889, against £900 in the corresponding week of 1895, a decrease of £11. The total receipts for the half-year amount to £16,149, against £16,119 for the corresponding period of 1895, an increase of £30.

**CONTINENTAL METROPOLITAN TRAMWAYS COMPANY (LIMITED).**—At the meeting of this Company last week the Chairman (Mr. B. H. Van Tromp), referring to the question of traction, said the Paris municipal authorities were becoming alive to the advantages of mechanical traction, and were pressing the various companies under their jurisdiction to submit their conditions for its general introduction. The Directors of the Continental Metropolitan Company had signified their willingness to adopt mechanical traction provided their concession was prolonged for another thirty years, but the Paris Council would not entertain this proposal. They had to submit other conditions which were at present being considered by the Council. The cost of working the tramways mechanically would be considerably less than at present, but they would have to allow for the amortisation of the capital in 14 years. They had, therefore, decided to ask the town for a subsidy of £16,000 a year to get over that difficulty.

**ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL COMPANY (LIMITED).**—The annual meeting of the shareholders of this concern was held on Monday last, Mr. John MacFarlan presiding. The chairman referred to the financial transactions mentioned in the abstract of the report given in our last issue, and contended that as a result of these operations the position of the Company had greatly improved. The depreciation shown in the accounts had been in 1893, £3,300. 0s. 10d.; 1894, £3,198. 4s. 7d.; and 1895, £2,554. 8s.—in all £9,052. 13s. 5d. The Directors had spent £2,511. 16s. 3d. during the year in putting down additional plant and in alterations to the old plant. The sales were more than double, while the amount spent on manufacturing, purchases, and wages, after deducting copper, was not much larger than in 1894, and the stock in trade in hand on December 31st was £2,194. 3s. 6d. more than on December 31st in the previous year. One of the difficulties connected with the business was that a large working capital was required. In other industries, as a rule, the raw material was cheap, but in their business the raw material was very expensive, and while they had to purchase for cash, they were compelled to sell at three months credit, according to the conditions of the trade. At present a sum of £11,478. 9s. 5d. was locked up in copper stores and sundry debts. The value of the work done in 1893 was £3,194. 3s. 4d.; in 1894, £8,130. 10s. 10d.; and in 1895, £17,052. 12s. 3d., which went to show that some progress had been made. They had received as many as 110 repeat orders from one firm, and had again secured the Imperial Railway's contract for the present year, and also contracts with other important manufacturing firms in Germany. They had, in addition, supplied the Government with a certain quantity of goods during the past year, concerning which they had not received a single complaint. Many improvements had been made during the past year, the small tube trade having been developed to a considerable extent, and they could now produce tubes from one-eighth of an inch up to 7ft. in diameter. The number of orders that they had in hand precluded them from fixing an early date for delivery, and in some cases they were compelled to refuse good paying work. The sales for the current year, up to the 19th inst., amounted to 59¼ tons (of the value of £5,648), compared with 40¾ tons (of the value of £3,706) last year. A further sum of £25,000 was required in order to carry out certain necessary extensions of the plant which the Directors considered urgent, and also to pay £4,200, being balance of the final instalment on the property of the Austrian Company. In conclusion the Chairman stated that negotiations had been begun for the working of their Austro-Hungarian patents.

**GREAT NORTHERN TELEGRAPH COMPANY.**—Notice is given that the coupons for the year 1895 (No. 36) on this Company's shares should be presented for payment at the offices of Messrs. C. J. Hambro and Son, 70, Old Broad-street, E.C.

**HASTINGS AND ST. LEONARD'S-ON-SEA ELECTRIC LIGHT COMPANY (LIMITED).**—The annual meeting of this Company was held at Hastings on Friday last, the Chairman (Mr. F. A. Langham) presiding. In moving the adoption of the report and accounts, the Chairman expressed regret at the character of the report, but said the prospects of the Company were good. During the year current was supplied to 8,199 lamps, an increase over the previous year of 988. The law expenses were £137 more than last year, £840 had been lost on the sale of installation fittings, and the bad debts came to £355 more than last year. Taking all these items into account, the net increase of income amounted to £537. Inclusive of these extraordinary items, the income had increased by £1,302, and the expenditure by £600, and the shareholders could thus see that they were not in a position to pay a respectable dividend. He was not sure that the new system of charging for current benefited either the Company or the consumers. Large consumers might derive benefit; but in order to obtain the full advantage electricity should be as liberally used as gas. The more current they used, the cheaper it would be. He regretted that the public lighting had been a great burden to the Company, as it entailed an absolute loss. They had carried out their contract to light the Front at a very low sum, and the loss on this account alone meant quite sufficient to pay a dividend, and until they could get rid of the contract, or obtain better terms, the Company could not be in a flourishing condition. The Directors had also under consideration the question of the price they should charge the Corporation for current. If they did not wish to continue the supply, the Corporation was bound to buy the fittings at a valuation, so that the shareholders would get some of their money back. Their private incandescent lighting business was sufficient to keep them busy. After the motion had been seconded, Dr. B. H. Allen expressed disappointment at the report, and attributed their position to want of economy. The motion was eventually agreed to.

**LIVERPOOL OVERHEAD RAILWAY COMPANY.**—The traffic receipts of this railway for the week ended 26th inst. amounted to £1,168. The amount for the corresponding week last year was £1,121. Increase £47.

**OXFORD ELECTRIC COMPANY (LIMITED).**—We are informed by the secretary that the recent issue of £5 Ordinary shares was over applied for.

**QUEEN ANNE'S MANSIONS LIGHTING AND HEATING COMPANY (LIMITED).**—A meeting of the debenture holders will be held on Monday at 251, Winchester House, E.C., at three o'clock, for the purpose of approving an agreement dated April 22nd, modifying a document dated May 16, 1895.

**STOCK EXCHANGE NOTICES.**—Applications have been made to the Stock Exchange Committee to allow the undermentioned stock to be quoted in the official list:—Crompton and Company (Limited), £82,850 Five per Cent. First Mortgage Registered Debentures; National Telephone Company (Limited), further issue of £229 471 Three and a-Half per Cent. Debenture stock; Sir W. G. Armstrong, Mitchell and Co. (Limited), 77,555 Four per Cent. Cumulative Preference shares.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).**—The Directors of this Company have decided, subject to final audit, after placing £3,000 to the reserve fund and £7,952 to the debenture redemption fund to recommend, at the forthcoming meeting of shareholders, the payment of 5s. 3d. per share, free of income tax, making, with the interim dividend paid in November, a total distribution of 3 per cent. for the twelve months to December last, the same as paid for 1894. This will give 5s. 3d. to the Ordinary, 3s. 9d. to the Preferred Ordinary, and 1s. 6d. to the Deferred Ordinary shares. This Company's traffic receipts for the week ended April 24th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,648.

**WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).**—The Directors of this Company have decided to recommend the payment of a dividend of 6s. per share on the First and Second Preference shares, and 1d. per share on the Ordinary shares for the six months ended December 31st last

THE METROPOLITAN ELECTRIC SUPPLY CO., LTD.,
offer the following
**WESTINGHOUSE ENGINES FOR SALE,**
owing to extensions and increase of H.P. required for larger Units.

All the Engines are in good condition and complete in all respects.

FIVE COMPOUND VERTICAL ENCLOSED ENGINES, each capable of indicating 320 H.P. when running at a speed of 250 revs. per minute, with a boiler pressure of 150 lbs. per square inch.

FIVE COMPOUND VERTICAL ENCLOSED ENGINES, each capable of indicating 250 H.P. when running at 280 revs. per minute, with a boiler pressure of 150 lbs. per square inch.

ONE COMPOUND VERTICAL ENCLOSED ENGINE capable of indicating 85 H.P. when running at a speed of 320 revs. per minute, with a boiler pressure of 150 lbs. per square inch.

The whole of the above Engines are fitted with variable expansion gear controlled by flywheel governors.

Permits to inspect may be obtained by application to the ENGINEER at 17, South-street, Manchester-square, W., who will give any further particulars.

THE AFRICAN DIRECT TELEGRAPH COMPANY,
Limited.
FOUR PER CENT. MORTGAGE DEBENTURE BONDS.

FIFTH DRAWING.

NOTICE is Hereby Given that in conformity with the conditions upon which the above issue was made, the undermentioned numbers of Debenture Bonds were this day Drawn at the Offices of the Company, Winchester House, Old Broad-street, in the City of London, in the presence of J. Denison Pender, Esq., one of the Directors, Henry Edward Plank, Secretary of the Company, and the undersigned Notary Public.

The said Debentures will be PAID OFF at par on the 1st JULY next, at PARR'S BANKING COMPANY AND THE ALLIANCE BANK, Limited, Bartholomew-lane, London, E.C., after which date the interest thereon will cease.

120 DEBENTURES of £100 each, numbered

## SITUATIONS VACANT AND WANTED.

WANTED, ELECTRICAL ENGINEER as Manager to go abroad; must have experience telephones, electric lighting, and transmission of power. Engagement five years.—Reply in first instance by letter to "BETA," care Davies and Co., Advertising Agents, Finch-lane, Cornhill, stating qualifications, experience, and salary required.

WANTED, thoroughly competent man as STOREKEEPER and TIMEKEEPER, for Yorkshire; must thoroughly understand installation and dynamo business. Highest references; good wages.—Address, "S. T.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ELECTRICIAN (practical) wishes to canvass for or superintend electric light work, or as Traveller for accessories. Small salary and commission. Age 23.—"ELECTRICIAN," 21, Evesby-road, Kilburn, N.W.

ELECTRICAL ENGINEER, with commercial, scientific, and practical experience, desires SITUATION, home or abroad.—"A. G. W.," 14, Lever-street, Manchester.

ELECTRICAL ENGINEER, aged 30, 11 years' experience, well up in general engineering, good draughtsman, with knowledge of foreign languages and customs, seeks engagement for directing installations work or management of central stations abroad.—Address, "E. M.," 121, Gower-street, London, W.C.

MAN (young) seeks EMPLOYMENT; can take charge of engine and machinery. Home or abroad. Over two years in last place with electric light plant. Good references.—"A.," 1, Clarkeson-villas, South Acton, W.

PARTNER WANTED by experienced Electrical Engineering Manager with a valuable and large business connection. Capital required, £2,000. Apply, 2196, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ELECTRICIANS.—NOTICE to EMPLOYERS.—Please note we have a number of First-Class ELECTRICAL MEN upon our Books. Kindly send us particulars of any VACANCIES you may have. We can introduce you, free of charge, to the best men now at liberty.

Address, CHAS. RICHARDSON and CO., Engineers' Bureau 342, Strand, London, W.C

PARTNERSHIPS.—ELECTRICAL ENGINEERS and others WANTING PARTNERS, or wishing to SELL, can be introduced to Clients with Capital; and GENTLEMEN Seeking Investments can obtain personally (or through their solicitors) particulars of bona-fide OPENINGS. Strictest confidence observed.—Address, CHAS. RICHARDSON and CO., 342, Strand, London, W.C.

**DOULTON & CO.,**
MANUFACTURERS OF
**PLUMBAGO CRUCIBLES**

FOR MELTING
Brass, Copper,
Malleable Iron,
Steel, Antimony,
Gold, Silver, &c.

*Depots:*
LIVERPOOL, MANCHESTER,
BIRMINGHAM,
ST. HELENS, LANCS., and PARIS.

**LAMBETH, LONDON, S.E.**

## WANTED, and FOR SALE.

PRICE LISTS WANTED.

Messrs. SWETE and BAKER, Electrical Engineers, will be glad to receive PRICE LISTS of ELECTRICAL PLANT, APPARATUS and FITTINGS, with best Terms for Cash and full export discounts, as they are about to carry out some important work at Johannesburg and in Rhodesia.

Communications to be addressed—Messrs. Swete and Baker, Box No. 647, care of Wm. Bettel, Esq., Goldfields Hotel, Johannesburg, S.A.R.

WANTED, LAMP TOPS with Platinum, Scrap Platinum, &c.—EDEY and Co., 256, Ferndale-road, Brixton, S.W.

DYNAMOS.

140 volts 90 amperes, E.P.S. Co., 740 revs.
100 volts 150 amperes, Statter, 1,300 revs.
100 volts 50 amperes, Gülcher.
65 volts 200 amperes, Siemens.
50 volts 40 amperes, Conrady.
50 volts 30 amperes, Elwell Parker.
50 volts 20 amperes, Siemens.
50 volts 15 amperes, Siemens.
55 Accumulators, 31 L. E.P.S.
12 Gas Engines from ½ H.P. to 12 H.P., by Crossley Brothers.
Gas Engine and Dynamo combined; new; for 15 16 c.p. lights. £45.
Send for list.
TUBE Co., LTD., 1000, Queen Victoria-street, E.C.

FOR SALE, a Direct-coupled Brush-Falcon ENGINE and VICTORIA DYNAMO, "C 2 and 6×5" combination, output 4,500 watts = 90 50 watt 16 c.p. lamps, speed 400 revs. per minute; almost new. Will sell cheap.—Can be seen at G. BAILEY'S, Southampton-mews, Southampton-row, Russell-square, London, W.C.

OFFERS WANTED for THREE 10-AMPERE THOMSON-HOUSTON ARC MACHINES, and for about 150 EIGHT-HOUR LAMPS, Each machine will maintain 50 lamps in series. Also for 4 SYNCHRONIZING PILLARS and 2 EXCITER PILLARS by Brush Co.—Apply SHEFFIELD ELECTRIC LIGHT AND POWER COMPANY (Limited), Commercial-street, Sheffield.

PLATINUM UTENSILS, SCRAP, LAMP TOPS.—Best prices given by Derby and Co., 44, Clerkenwell-road, London, E.C. N.B.—Platinum sold

ACCUMULATOR CHARGING.—C. H. CATHCART and CO., having plant specially adapted for this purpose, Charge Cells of all sizes promptly, thoroughly and cheaply. Terms on application. Accumulators on Hire for temporary lighting, experimental uses, &c.—3, Dorset-buildings, Salisbury-square, Fleet-street, E.C. (Telephone No. 65,266.)

## NOW READY, NEW EDITION.

# THE ALTERNATE-CURRENT TRANSFORMER

## IN THEORY AND PRACTICE. VOL. I.

By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S., M.R.I., &c. FULLY ILLUSTRATED. PRICE **12s. 6d.**, POST FREE.

***Five issues of the original Vol. I. were made and exhausted between September, 1889, and March, 1896.***

Since the issue of the First Edition of this work the study of the properties and applications of alternating electric currents has made enormous progress. . . . . The author has, accordingly, rewritten the greater part of the chapters, in the hope that the book will continue to be useful to the increasing numbers of those who are practically engaged in alternating-current work. Academic methods are avoided, and the necessities of the student who has to deal with the subject not as a basis for mathematical gymnastics but with the object of acquiring practically useful knowledge, have been fully considered.

**CHAPTER I.—Introductory.**

Faraday's Electrical Researches—Early Experiments on Electro-Magnetic Induction—Faraday's Ring Coil—Mutual Induction of Two Circuits—Faraday's Theories—The Induction of Electric Currents—Faraday's Lines of Force—Joseph Henry's Discoveries—The Production of Electric Currents by Magnets and Motion.

**CHAPTER II.—Electro-Magnetic Induction.**

Magnetic Force and Magnetic Fields—Definitions of Magnetic Quantities—Magnetic Force near Conductors—Typical Cases—Magneto-Motive Force and Magnetic Induction—Magnetic Potential—Tubes of Magnetic Induction—Faraday's Law of Induction—The Magnetic Circuit—Magnetic Resistance and Reluctance—Curves of Magnetisation—Determination of Permeability—Magnetic Hysteresis—Dissipation of Energy by Hysteresis—Variation of Hysteresis with Temperature.

**CHAPTER III.—The Theory of Simple Periodic Currents.**

Variable and Steady Flow—Current and Electromotive Force Curves—Simple Periodic Curves—Compound Periodic Curves—Fourier's Theorem—Mathematical Sketch of Fourier's Theorem—Analysis of Complex Curves—Simple Periodic Currents and Electromotive Forces—Mean-Square Value of a Periodic Current—Inductance and Inductive Circuits—Faraday's Experiments on Self-Induction—Electro-Magnetic Momentum—Coefficient of Self-Induction—Electro-Magnetic Energy—The Unit of Inductance—The Current Equation—Logarithmic Curves—Time Constant of a Circuit—Instantaneous Value of a Periodic Current—Graphic Representation of Periodic Currents—The Mean Value of the Power of a Periodic Current—The Theory of the Wattmeter—Impedance of Branched Circuits—Mutual Induction of Two Circuits—The Flow of Periodic Currents in Circuits having Capacity—Shunted Condenser in Series with Inductive Resistance—Representation of Periodic Currents by Polar Diagrams—Initial Conditions on Starting Currents in Inductive Circuits.

**CHAPTER IV.—Mutual and Self-Induction.**

The Researches of Joseph Henry—Mutual and Self-Induction—Induction at a Distance—Induced Currents of Higher Orders—Induction Effects by Transient Electric Currents—Theory of Induction Coil—Experimental Confirmations—Duration of Induced Currents—Magnetic Screening Action of Metallic Masses—Sonometer and Induction Balance—Transmission of Alternating Currents through Conductors—Prof. Hughes' Experiments—Distribution of Alternating Currents in Conductors—Electro-Magnetic Repulsion—Elihu Thomson's Experiments—Electro-Magnetic Rotations—Growth of Magnetic Induction in Magnetic Circuits—Symmetry of Current and Induction.

**CHAPTER V.—Dynamical Theory of Induction.**

Electro-Magnetic Theory—Electric Displacement—Maxwell's Theory—Displacement Currents and Displacement Waves—Mechanical Illustrations—Theory of Molecular Vortices—Comparison of Theory and Experiment—Velocity of Propagation of Electro-Magnetic Disturbances—Values of "$p$"—Vector Potential—Electrical Oscillation—Discharge of Leyden Jar—The Function of Condenser in the Induction Coil—The Alternative Path Experiments—Impulsive Impedance—Hertz's Researches—Resonance of Circuits—Interference Phenomena—Identity of Light and Electro-Magnetic Waves—Confirmatory Experiments—Experimental Determination of the Velocity of Propagation of Electro-Magnetic Waves—Recent Views.

**CHAPTER VI.—The Induction Coil and Transformer.**

General Description of the Action of the Transformer or Induction Coil—Experimental Determination of the Form of Current and Electromotive Force Curves—Curve Tracers—Discussion of Transformer Diagrams—Current and Electromotive Force Curves in Various Cases—Harmonic Analysis of Transformer Curves—Curves of Magnetic Induction—Power and Hysteresis Curves—Experimental Determination of Iron Arc Losses in Transformers—Practical Use of the Wattmeter—Efficiency Curves of Transformers—Secular Change in Hysteresis Loss in Transformers—Current Rushes into Transformers at Moment of Making Connection with the Circuit—General Theory of Transformer Action—The Power Factor—Importance of Large Power Factor—Open and Closed Circuit Transformers—Regulation and Secondary drop in Transformers—Magnetic Leakage—Control of Copper and Iron Losses in Transformers—Heat Radiation from Transformers—Transformer Specifications.

# PRITCHETT ACCUMULATORS

**PLANTÉ TYPE.**

**From the ELECTRICAL STANDARDIZING INSTITUTION, LONDON.**

"The Cells we use for standardising purposes were supplied to us by yourselves in September, 1892, and have been in constant use ever since.

"The normal maximum output was stated to be 250 amperes per cell, that is, nearly 18 amperes per positive plate nine inches square, but we sometimes discharge them for short periods at three times this rate, so that each positive plate gives 54 amperes; indeed, they are occasionally deliberately short-circuited. Up to the present time no repairs have been needed, and they continue to do their work satisfactorily.

"You agreed to supply us with Cells which could be practically short-circuited without undue deterioration, and this we consider you have done."

**TWO RECENT TESTIMONIALS.**

*Price Lists and Trade Terms on Application.*

**From Messrs. F. H. ROYCE & CO., Ltd., MANCHESTER.**

"We have very great pleasure in testifying to the excellence of your Accumulators. We have, during the last few years, purchased a very considerable number of you as you know, and have always considered them, as we do now, the best in the market owing to the very great mechanical strength and large surface of the plates.

"If it would be of service to you at any time, we have no doubt we could get many of our customers using these Accumulators to give equally strong testimony as to their excellent features."

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 938. [Vol. XXXVII. No. 2.] FRIDAY, MAY 8, 1896. PRICE SIXPENCE.

## NOTES.

THE two most interesting electrical exhibits shown at the Royal Society *soirée* on Wednesday evening were Prof. EWING'S beautiful apparatus for rapidly making permeability measurements, a description of which will be found in another column, and the novel resistance boxes shown by Mr. E. H. GRIFFITHS and Mr. F. W. BURSTALL, which we hope to fully describe in a later issue. Mr. CAMPBELL SWINTON was allotted an entire room for the purpose of giving demonstrations of the Röntgen radiography, and Mr. HERBERT JACKSON, of King's College, was also in evidence with his focus tube.

A PRETTY little exhibit, due to the Rev. F. J. SMITH and Mr. VERNON BOYS, consisted in geometric wall brackets and geometric steady blocks. The object of these brackets is to provide wall supports with definite position for physical apparatus. Three small projections are fixed to the wall. Of the two upper ones, one is furnished with a triangular indentation, the other with a V-groove, the third having a vertical flat surface. The brackets are furnished at the top with hemispherically-ended screws, which drop into the recesses in the upper blocks, and at the bottom with a third screw, which rests against the flat projection. Three points of contact are determined by the sphere-and-triangle support, and these rigidly determine two in the sphere-and-cup support and one on the wall plate. Thus the system is completely and rigidly determined. The same idea is carried out in regard to the geometric steady blocks.

ALUMINIUM is probably the last metal to be recommended for fusible cut-outs. It will fuse readily enough, but it will not cut-out, at least not with any degree of promptness; it prefers to remain as a conducting filament of red-hot molten metal bridging across the terminals. At the Royal Institution last Tuesday Mr. VERNON BOYS showed a very effective experiment to illustrate the reluctance of a melted aluminium wire to break up into detached drops, as any self-respecting cylinder of liquid ought to do. Some eight or ten inches of fine aluminium wire were secured between two binding pillars, and a current sufficient to raise the wire to bright red heat was gradually switched on. While the wire was in this perfectly molten condition, the temperature being well above the melting point, a magnet pole was moved about in its neighbourhood. The liquid filament was attracted or repelled at will, and when sufficiently powerfully repelled it looped itself with the evident intention of getting into such a position that it would be attracted. The intention was fatal, for the moment the loop was completed the points of contact coalesced and the liquid system instantly collapsed.

As another instance of the highly-developed capillary properties of liquid aluminium, Mr. BOYS showed how enormously large are drops of molten aluminium in comparison with water or mercury drops of the same shape. In liquid aluminium the surface tension is very high, while the density, as compared with other metals, is very low. Consequently drops of aluminium approximate to a sphere in much larger sizes than in any other known metal, except perhaps magnesium. It is to this that the apparent pastiness of molten aluminium is due. That there is no real pastiness is quite evident from the fine lines which it will take in making a casting.

A DISCUSSION extending over three evenings is apt to become distinctly wearisome and sadly irrelevant, as those who were present on the occasion of the recent house-wiring debate at the Institution of Electrical Engineers know to their cost. It is doubtful, moreover, whether any scientific or engineering subject under the sun is worth so prolonged a tossing "upon the arguments of counsel." The Institution of Mechanical Engineers, however, did well not to keep the debate on steam-superheating within too narrow time limits. Regarded as a matter affecting modern steam practice, the subject is one of prime importance, and quite as worthy of the large amount of time devoted to it as anything we know of. But it certainly was regrettable that so long an interval as three months should have elapsed between the reading of Mr. PATCHELL'S Paper and the resumption of the discussion. Some of the later speakers had obviously forgotten the contents of the Paper, while others missed the chief point which its author had in view.

AT Maiden-lane station Mr. PATCHELL has found that the use of superheaters on a portion of the boiler plant results in both a higher economy and a greatly improved duty. More power can be got out of a given weight of fuel, and more steam out of a given space in the boiler room. It is true that the steam does not reach the engines in a superheated state, owing partly to the admixture of steam from the other

Digitized by Google

boilers and partly to radiation. But it is quite beside the mark to say that the apparatus is not a superheater. It is also beside the mark to say that Mr. PATCHELL has devoted too much attention to the boiler gain and too little to the engine gain. For the laudable purpose of clarifying matters in text-books and in class-rooms there may be some advantage in saying that, theoretically, superheating gives only an engine gain. What the practical man wants to know is what it will do practically and on an £. s. d. basis; and as in practice we have not succeeded in getting superheated steam in the engine on the working stroke, and but rarely get it at the stop-valve, it is more to the point to pay attention to the improvements which a superheater brings about in the boiler plant, in the better utilisation of the heat from the furnace, and in the extra duty in evaporation.

WHATEVER may be the measure of success attending gas-engine electric supply stations on the Continent, those at home are not, it would seem, unqualified successes. At Coatbridge the gas plant has been replaced by steam, at Morecambe the station was declared a public nuisance and was for some time shut down, while at Belfast it has practically been decided to erect a steam-driven station capable of filling the future requirements of that city. The Belfast gas-engine station was originally the initial stage in a scheme of gas-power sub-stations, a system of which the late Mr. DENNY LANE was the first and most powerful advocate. It would be rash to infer from these three deviations from success that gas-power electric supply stations must of necessity fail; but it is highly probable that for some time to come both capitalists and engineers will draw the practical conclusion that this class of installation should be left severely alone. Pending further particulars as to why the Belfast municipal authorities do not propose to proceed with their original scheme, we cannot but regret that the matter has taken so unfortunate a turn. Coatbridge had elements of failure not essentially gaseous; Morecambe was too rough-and-ready a pioneer job to ensure permanent success; but of Belfast we had hoped that its sound modern design and solid construction would place the gas-engine station system on a secure and lasting footing. Unfortunately, the outcome of the Belfast venture seems to point to the temporary failure of this type of electric supply station, at any rate under conditions met with in this country.

THE exhibition now being held at the Crystal Palace, to which further reference is made in another column, is accurately described as horseless, for the greater number of exhibits are merely ordinary carriages with the horses taken out of the shafts. These are supposed to be of historic interest, to mark the era of quasi-civilisation which has led up to the glorious age of motor cars. As to the motor cars themselves, we saw a considerable variety within the building, and a couple running in the grounds. One of these latter was propelled by steam and the other by petroleum spirit. Both the one and the other was preceded by a great wave of noise, rendering the oft-repeated injunction to "Beware of the Horseless Carriages" quite superfluous, while the spirit-propelled vehicle had an equally pronounced wave of odour behind it. That is how we first learned it was driven by spirit. When it stopped to take up a fresh cargo of adventurous passengers its spirit was even more in evidence. Never did a restive steed prance with more vigour than did that petroleum-driven carriage; it was as if the spirit of ST. VITUS himself had got into the works. Something ought to be done to subdue the impatience of this benzolene steed when it is required to stand still a little while, for the vigorous jiggle which it maintains all the time is by no means inviting to a ride. Electric cars in active operation were conspicuous—by their absence.

**Royal Society.**—Among the Papers down for reading on Thursday was one by Prof. Gotch, F.R.S., and G. J. Burch on "The Electromotive Properties of *Malapterurus Electricus*."

**The Evaluation of a Unit.**—It seems that in Vermont, U.S.A., there exists an unrepealed law to the effect that "one bushel and three-quarters of a peck shall be deemed a bushel."

**Appointment.**—Mr. E. W. Dickinson, late of the Bolton Corporation Electricity Works, has been appointed engineer to the Trinidad Electric Light and Power Company (Limited), Port of Spain, Trinidad.

**The "Sir John Pender" Gold Medal.**—The "Sir John Pender" gold medal, which is awarded annually to the best student of the electrical engineering department of the Glasgow and West of Scotland Technical College, has been won by Mr. Alex. H. Weddell.

**Compagnie Française des Cables Télégraphiques.**—We learn that the French cable steamer "François Arago" is at Havre refitting, and that she will be chartered by the Compagnie Française des Cables Télégraphiques to repair their West Indian system of cables.

**Terrestrial Magnetism.**—According to "Terrestrial Magnetism," M. Moureaux has been requested by the Imperial Russian Geographical Society to investigate the cause of an anomaly in the distribution of terrestrial magnetism, which certain observations have revealed in Southern Russia.

**Electric Railways for Brussels.**—According to a Brussels newspaper, the Belgian Government has determined to unite the two great terminal stations in that city by six underground tracks, and to construct a central station and a girdle line around the city. Two of the underground lines are to be worked by electricity.

**South-West London Polytechnic Institute.**—The governing body of this Institute have decided to hold the first annual conversazione on Saturday next, May 9th. Among other special items of interest may be mentioned the demonstrations and experiments of Messrs. Edser and Clark on "New Photography," including some negatives of fractures and necrosis.

**A Pacific Cable.**—A Reuter's telegram states that a Bill for the construction of a United States-Hawaii-Japan cable has been approved by the Senate Committee, and authorises the U.S. Postmaster-General to contract with any company to lay the cable with an annual subsidy not to exceed $160,000. The report estimates the cost of the cable at $3,400,000, and the annual maintenance at $586,000 for the first five years.

**Bacteria and Electric Currents.**—On page 71 of our issue of November 15th last, we alluded to some interesting and some what amusing experiments by a Dr. Waller on the behaviour of tadpoles when exposed to the influence of the electric current. In the *Comptes Rendus* for April 20th, M. L. Lortet, in a communication on "The Influence of Induced Currents on the Orientation of Living Bacteria," describes how he placed some bacteria in a drop of liquid, through which he passed in various

Digitized by Google

directions the current from an induction coil; they invariably arranged themselves so as to become parallel to the direction of the current.

**Polyphase Motors in a Shoe Factory.**—The operation of shoe factories by electricity seems to be making steady headway in America. The General Electric Company of America is about to undertake the electrical equipment of a large shoe factory in Norway, Me. Seven non-synchronous multiphase motors, aggregating 100 H.P., will be put in. The current will be taken from the 250-kilowatt three-phase generator recently set up in its station by the Norway Electric Light Company.

**Three-Phase Patent Litigation in Germany.**—The three-phase patent of the Helios Company of Cologne, against which an action was brought a little time ago by Messrs. Schuckert and Co., the Allgemeine Elektricitäts Gesellschaft, Siemens and Halske, and Lahmeyer and Co. has been upheld by the Imperial Patent Office and the application dismissed with costs. Some three months ago the "Reichsgericht," the highest Court in Germany, dismissed a similar action against the same patent. The patent in question is a Zipernowsky-Déri patent. The firms mentioned have lodged an appeal against the decision of the Patent Office.

**The London Electric Supply Business.**—A well-written and accurate *critique* of the London electric supply business, from the point of view of the investor, is to be found in the current number of the *Investors' Review*. Tables are given showing the Board of Trade units sold during 1895, the dividends paid since 1891, the sums set aside for depreciation out of revenue, and the present prices charged for the Board of Trade unit and the maximum charges permitted. Much space is devoted to the finances of the City of London Electric Lighting Company. At the conclusion of the review the writer expresses his belief that "the companies appear to have a good future before them, and probably the present range of dividends will be improved upon," an opinion in which we entirely concur.

**International Congress of Electrical Engineers at Geneva.**—On the occasion of the Swiss National Exhibition at Geneva, the Society of Swiss Electrical Engineers has resolved to hold, during the month of August, an International Congress of Electrical Engineers, and has now sent invitations to different foreign societies. The Congress will last four days and the following subjects have been included in the programme:—(1) Magnetic units and their nomenclature; (2) Photometric units and their nomenclature; (3) Long-distance transmission of energy and its distribution by continuous and alternating currents; (4) Protection of high-pressure circuits from atmospheric discharges; (5) Disturbances caused by electric tramways. In connection with the Congress there will be excursions into the Jura and central districts of Switzerland for the purpose of inspecting various important electrical plants.

**Motor Car Club.**—A club has been founded to promote the manufacture and use of motor-carriages and other road vehicles, and an inaugural dinner was held at the Imperial Institute on Friday. Members of the House of Lords (who are discussing Lord Harris's Bill and the proposed amendments thereto) were invited to judge of the merits and capabilities of various types of motor carriages and cycles, which will be on view at the Institute during the exhibition which opened on Saturday. Several electrical exhibits are to be included shortly, amongst which will be an electric carriage, constructed by Messrs. Thrupp and Maberley, with a motor designed by M. Julien, of storage battery fame. At the dinner, in response to the toast of the "British Motor Car Industry and Club," Mr. H. J. Lawson, whose name is so well known in connection with the introduction of the bicycle into this country, responded, and referred to the remarkable exhibits which they had inspected, and claimed for them that they were the most wonderful inventions of this century. Arguing from the immense success of the cycle industry, which he had founded 20 years ago, the speaker stated that the horseless carriage industry, which had met with the same ridicule and opposition as its precursor had done, was now gradually assuming its place in the list of British industries.

**Royal Institution.**—The annual meeting of the members of the Royal Institution was held last week, Sir James Crichton-Browne presiding. The annual report of the Committee of Visitors for the year 1895 was read and adopted. The real and funded property now amounts to above £100,000, entirely derived from the contributions and donations of the members and of others appreciating the value of the work of the Institution. During 1895, 72 new members were elected, and 63 lectures and 19 evening discourses were delivered. The books and pamphlets presented amounted to about 260 volumes, making, with 594 volumes purchased by the managers, a total of 854 volumes added to the library in the year. The following gentlemen were unanimously elected as officers for the ensuing year:—President: the Duke of Northumberland; Treasurer: Sir James Crichton-Browne, F.R.S.; Secretary: Sir Frederick Bramwell, F.R.S.; Managers: Sir Frederick Abel, Sir Benjamin Baker, Mr. John Wolfe Barry, Lord Halsbury, Mr. Charles Hawksley, Dr. John Hopkinson, F.R.S., Mr. Victor Horsley, F.R.S., Mr. Willam Huggins, F.R.S., Lord Kelvin, F.R.S., Mr. Alfred B. Kempe, F.R.S., Mr. George Matthey, F.R.S., Mr. Ludwig Mond, F.R.S, Sir Andrew Noble, F.R.S., Earl Percy, and Mr. Basil Woo ld Smith; Visitors: Mr. Gerrard Ansdell, Sir James Blyth, Mr. Arthur Carpmael, Sir William James Farrer, Mr. Carl Hagg, Sir Francis Laking, Mr. Hugh Leonard, Mr. James Mansergh, Mr. Lachlan Mackintosh Rate, Mr. Felix Semon, M.D., Mr. Henry Virtue Tebbs, Mr. John Isaac Thornycroft, F.R.S., Mr. Thomas Tyrer, Mr. John Westlake, Q.C., and Mr. James Wimshurst.

**Applied Electro-Chemistry.**—In his second Cantor lecture on this subject at the Society of Arts, Mr. Swinburne, after showing some pretty experiments illustrating the dissociation hypothesis and the phenomenon of electric osmosis, proceeded to describe in some detail various electrolytic processes of copper refining, the Ashcroft process for winning zinc from the Broken Hill ores, and the best-known electrolytic methods for making caustic soda and bleach, referring incidentally to the deposition of lead, sewage purification, and to an ingenious but impracticable electrolytic meter, based on the principle of electric osmosis. In connection with the electrolytic refining of copper, the lecturer pointed out that in this country we preferred using $\frac{1}{2}$-volt cells having a number of anodes and cathodes in parallel, a system involving multitudinous connections; whilst in the United States, at the Anaconda Works, for instance, they used 100-volt vats, with a succession of crude copper plates intervening between the anode and cathode proper. The plates, of course, acted on one side as cathodes, and received pure copper, and on the other as anodes, and dissolved away. To prevent the process from going too far, and the *pure* deposited copper from being eaten away, a very ingenious device was adopted at the Anaconda Works. Sheets of paper were rivetted on to the cathode faces by means of copper rivets; these rivets afford sufficient conductivity to enable the job to be started, and the copper deposit soon spread from the rivets all over the surface of the paper. When the anode face of the bar was completely eaten away further action on the pure deposited copper was stopped by the intervention of the paper wall.

**Electrical Separation of Tellurium from Copper Residues.**—A method for the separation of tellurium from copper residues is described by Mr. Cabell Whitehead in the *Journal* of the American Chemical Society. In the electrical refining of copper the washings from the gold residues contain the tellurium as tellurous oxide or sulphate. The tellurium may be obtained from these either by precipitation with copper or by passing sulphurous anhydride through the solution. It may be finally purified by distillation in hydrogen. When a solution of sodium tellurite is added to a solution of an ammonium salt, a white precipitate of tellurous anhydride is thrown down, which becomes granular on boiling. A small amount of tellurium or of some metal which can be precipitated by sulphurous anhydride remains in solution; this soluble portion is still under investigation. Potassium ferrocyanide does not react with tellurium chloride at once, but after a few hours prussian blue is formed. When tellurium is heated with aluminum the two combine with explosive violence, forming a chocolate-coloured compound difficultly fusible, which has the

Digitized by Google

composition of $Al_2Te_3$. It is hard and brittle, and can readily be ground to powder; when exposed to moist air it is decomposed, and hydrogen telluride is slowly evolved; when thrown into water it is rapidly decomposed. Tellurium is readily deposited by an electric current either from an acid or alkaline solution. It has been found possible to separate tellurium from copper by adding an excess of sodium hydroxide and about 3 grammes of potassium cyanide for each gramme of copper present, and passing an electric current through the solution, when the tellurium is thrown down as a black, non-adherent precipitate, which can readily be filtered off; the solution can then be slightly acidified with sulphuric acid, and the copper estimated in the usual way by electrolysis.

**The "Okinawa Maru."**—The Japanese Government cable steamer "Okinawa Maru" left the Telegraph Construction and Maintenance Company's works at East Greenwich on Monday evening, the 4th inst., for Japan, after loading some 236 knots of cable. This length completes the order for 800 knots secured by that Company last autumn. The first portion was shipped and despatched to Nagasaki in December last in the chartered steamship "Ayr." We understand that this cable is intended to be laid between Japan and Formosa *viâ* the Lu Chu group of islands, two of which will be connected up. Great reticence on the subject is, however, maintained by the Japanese Government. The "Okinawa Maru" proceeds to Nagasaki under the command, in the illness of her captain, of Capt. Lacy, who is the solitary Englishman on board, the technical staff and ship's officers and crew being all Japanese. The cable and electrical stores are in charge on the outward passage of Mr. S. Nishikata. During her stay off the Telegraph Construction works at Greenwich the "Okinawa Maru" has been visited and critically examined by a large number of cable men. The general verdict would seem to be that she is somewhat too much hampered about the decks for cable work, and that more space should have been provided below abaft the gear for stowing buoys, coiling ropes, &c. A flush deck, such as that of the "Britannia," for example, would have been preferable. The testing room is exceedingly spacious and well ordered, and is placed where every ship's testing room should be—namely, on the upper deck amidships. The chief electrician's cabin is most conveniently situated just outside the testing room. The saloon and cabin accommodation of the vessel leave nothing to be desired. It must be remembered that some 600 knots of cable manufactured for the Japanese Government by the Silvertown Company were shipped to Nagasaki some weeks back in a cargo steamer, the "Sarpedon." So far the destination of that cable has been kept secret.

**Röntgeniana.**—A steady stream of Röntgeniana continues to flow throw the Académie des Sciences. In the last number of the *Comptes Rendus*, M. R. Colson describes some experiments devised by him with a view of determining whether X-rays impress photographic plates directly or by means of a transformation due to the support or to the sensitive layer itself. He concludes that the rays act directly.——M. F. P. le Roux, in a memoir "On the Heterogeneity of the Rays emitted by Crookes' Tubes and the Transformation of the Rays by Screens," relates some curious results obtained by him in his first attempts at radiography. Pieces of metal were apparently more easily traversed the thicker they were; cardboard was relatively opaque, though when placed on a piece of metal the two were transparent; the gelatine was tinted red. The majority of M. Roux's conundrums were solved for him by M. H. Becquerel's discovery that the so-called X-rays, due to phosphorescence, traverse metals more easily than those derived from ordinary Crookes' tubes, and are reflected. The colouration of the gelatine is, M. Roux argues, due to a sifting effect of the cardboard screen. He suggests the term *hyperdiabatic rays* in lieu of the more common one.——MM. L. Benoist and D. Hurmuzescu find that:—All things being equal, the rate of discharge of a charged body varies as the square root of the density of the gas in which it is immersed. These experimenters put forward the hypothesis that the behaviour of electrified bodies under the influence of Röntgen rays is due to the expulsion by the body under their influence of the molecules of gas condensed on the surface or occluded at a certain depth.——M. A. Lafay, in a further communication "On Electrified Röntgen Rays," describes how he placed an insulated metal screen, connected to an electrometer or to an electroscope, inside a Faraday box of thick lead, and directed on to the screen a cone of X-rays, the rays entering the box through an aperture covered by some electrified conducting membrane. A charge of the same sign as that on the membrane was developed on the screen, the action resembling that which would occur if the electrified membrane and the screen had been connected by a badly-insulated highly-resisting wire. M. Lafay finds that the transference of the charge is the more rapid the more transparent the membrane. In the course of these investigations M. Lafay found that on suppressing the electrified membrane the electrometer, as a rule, showed the existence of a slight + charge on the screen; but the charge was from 20 to 30 times less than that obtained with "electrified rays," which gave an appreciable magnetic deflection.

**Recent Chemical Progress.**—In his last lecture on this subject at the Royal Institution last week, Prof. Dewar pointed out that a true solvent for aluminium having been found in cryolite which melts at a moderate temperature, we are enabled by electrolysis to break up the oxide, and deposit pure aluminium on the cathode, and this metal, owing to its great reducing properties, can be used to effect the separation of other metals, such as chromium and tungsten from their oxides. From the time of Davy it has been known that the alkaline metals could be obtained by electrolysis, but perhaps the greatest advance which has been made in the process from the chemical point of view is the use of a moving electrode which removes the alkali from the solution as fast as it is separated. It is well known that in all cases of electrolysis there is a powerful back electromotive force due to the tendency of the separated ions to recombine. This tendency was overcome by Daniell in his well-known cell by causing the substitution of copper for the separated hydrogen, which copper was deposited on a copper plate. In Groves's battery, nitric acid is used as a depolariser, and in all the modifications of these two batteries which have been introduced depolarisation has been effected by the introduction of some substance to combine chemically with one of the separated ions. But in the Castner process for the production of caustic soda and chlorine by electrolysis, travelling cathodes of mercury are employed, which combine with the sodium, and remove it from the electrolytic tank as soon as it is separated, and pass it into another vessel in which the sodium amalgam is decomposed with the formation of caustic soda, while the mercury passes on and is ready to be used again. By suitable connections the energy due to the formation of caustic soda is made to yield a current which supplements the electrolytic current. Thus not only is polarisation prevented, but the tendency of the ions to recombine, which would have caused it, is made to assist the electrolytic process. In electrolysis it is not only the back action of hydrogen and the metals which are liberated at the cathode which has to be overcome, but the effects of the anions must be guarded against. In copper we have a metal which is valuable in many instances, for it is not only readily oxidised by electrolytic oxygen, but its oxide is reduced with equal facility by the hydrogen evolved, and in many processes this fact has been taken advantage of. Groves in his gas battery attempted to utilise the combination of oxygen and hydrogen for the production of an electric current, and Ludwig Mond has recently tried to improve this battery which, for many reasons, was not commercially useful. Many attempts have been made to obtain electricity direct from the combination of carbon and oxygen. Coal is not a good conductor, and some fused oxidising agent is necessary as an electrolyte, so that there are difficulties in the way of using carbon as the positive electrode. Carbon monoxide, however, can be readily produced, and perhaps the solution of the problem will be found in some modification of Grove's battery in which carbon monoxide will replace the hydrogen. Passing on to the metals of the rare earths, the lecturer stated that the oxides of lanthanum, zirconium and thorium converted more heat into light than any other known substances, and illustrated the process of the manufacture of an incandescent gas mantle. Chlorate of potash, which was so much used by chemists as a source of oxygen, is now produced electrolytically.

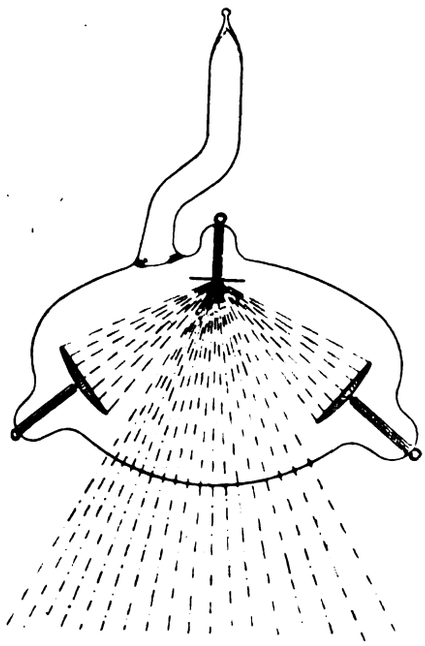
## FOCUSSING TUBE FOR USE WITH ALTERNATE CURRENTS.

BY A. A. CAMPBELL SWINTON.

In Prof. Röntgen's second communication to the Würzburg Physico-Medical Society, published in your issue for April 24th, he states that he is constructing a special form of vacuum tube for use with alternate currents from a Tesla transformer. For those whose laboratories are supplied with alternating current, but who cannot readily obtain continuous current, a tube suitable for use with Tesla current is an advantage. The annexed illustration shows such a tube which I had made nearly two months ago. The two curved aluminium discs serve alternately as cathode and anode according to the



direction of the current, each focussing its cathode rays upon an identical portion of the flat platinum reflector. If carefully made, so that the foci of the two discs are exactly in the same point, the tube will be found to work well.

By connecting both discs together and using them as cathode, and employing the platinum as anode, the same tube will answer for Rhumkorff currents.

## THE COMBINED ALTERNATE-CURRENT AND CONTINUOUS-CURRENT SYSTEM OF SUPPLY AT BRIGHTON.

Probably the most interesting of the many features of interest connected with the electric lighting of Brighton is the system of supplying the outlying districts during the greater portion of the 24 hours with continuous currents, and during the few hours of heavy load with alternate currents. The idea is in itself refreshingly original, but an engineer cannot afford to be original unless he can be assured of a substantial gain and of practical success. The figures relating to the coal consumption at Brighton for the past year will, we think, convince him that a substantial gain is achieved, and a few particulars about various subsidiary devices will be equally convincing as to practical success.

From the sketch-map of the town it will be seen that by far the greater portion of Brighton is supplied on the ordinary continuous-current (three-wire, 115 volt) system. In Fig. 1 the network served on the dual plan is given in greater detail. What is done is briefly as follows:—In the outlying quarters, known as the Preston and Lewes-road districts, a high-pressure alternate-current ring main is laid. The ring main is tapped at intervals by transformers, the secondaries of which are connected to the 3-wire distributing network. The high-pressure ring main and the distributors are, we may here remark, both of the paper-insulated concentric type. Into each of the two transformer sub-stations nearest to the town network, a low-pressure distributor is run. Means are thus available for connecting the districts at will with the ordinary town continuous-current network, or with the high-pressure alternate-current feeders coming direct from the alternators at the central station.

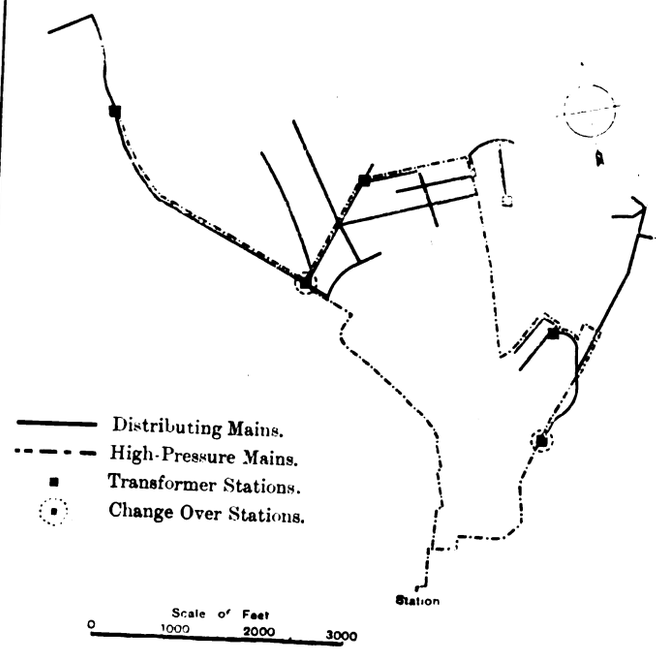


FIG. 1.—Map showing Network worked on the Combined System.

The whole system has worked perfectly satisfactorily since it was started in 1894, and with marked economy in coal. Although there are a few business streets in the area supplied on the combined plan, the main demand will, in all probability, always come from private houses and street lamps.

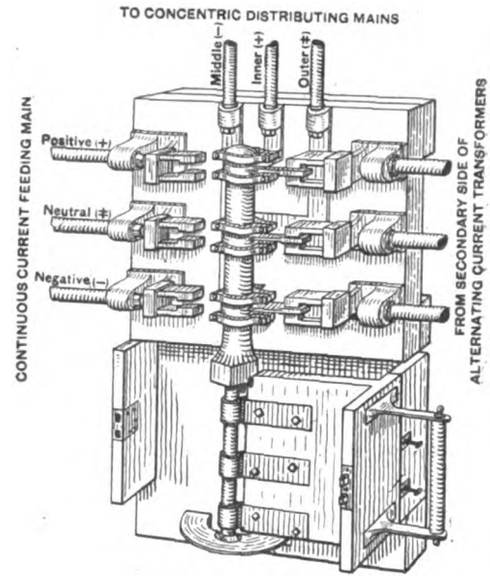

FIG. 2.—Interlocking "Change-Over" Switch.

The continuous-current is only supplied between the hours of 11 p.m. and sunset the next day, and it will thus be obvious to any central station engineer that owing to the extremely small load the whole supply can be carried out through the distributors without the aid of special continuous-current feeders. When, however, the load begins to increase the scattered network requires more regular feeding arrangements.

Digitized by Google

Of course the difficulty could be met by employing one or other of two expensive luxuries, to wit, a new station built specially to supply the outskirts of the town, or very heavy feeders. "Boosters" also might be used, but whether they would give a greater measure of practical success than the system actually in use is problematical.

It will be evident, from what we have described, that some very certain system of interlocking had to be devised before a public supply could be commenced on this plan. In this matter Mr. Arthur Wright has had the advantage of the very valuable assistance of his distribution superintendent, Mr. R. C. Quin, who has worked out a very complete system of keys and locks, which prevents any distributor being connected to the secondary of a transformer, while the distributor is connected to the continuous-current network, and which locks and prevents the changing-over switches being turned from the alternating source of supply to the continuous as long as there is a single transformer in the district connected to its network. A view of a change-over station switch is given in Fig. 2. On coming to the station in the evening the bicycle switchman finds the switch connected to the three-wire town main on the left. He pulls the lever over to the right, connecting the distributors of the section governed by the change-over station to the secondary of the live transformer and disconnecting the entire section from the continuous-current supply. He locks the switch, and in doing so releases the keys. With these keys he is able to release the switches of the transformers in the other stations belonging to the section, and to thus connect fresh alternate-current feeding points to the distributors. In the evening he commences at the feeding-stations, switching them off in succession and gradually throwing the entire load on to the change-over station. As he switches over at the sub-stations he locks the switch in position out of harm's way, and in so doing releases a key. He finally arrives at the change-over station with his due quantum of "open, sesame," by means of which he is able to release the switch and pull it over to the left, once more connecting the district to the town mains, shown in Fig. 3.

At the moment of changing over from one system to another, there is, of course, a momentary blink in the lights; but as this usually occurs before dusk, and about 11 p.m., it is hardly noticed. There are nearly 100 consumers supplied on this dual system, with some 4,000 lamps connected. The accompanying curve (Fig. 4), giving the number of pounds of Welsh coal used at Brighton per unit sold, shows how economical at all times of the year a station worked on this system can be. Had it been necessary to feed six transformers day after day during the whole of the 24 hours with magnetising current, the coal consumption during the dog-days would have exhibited a very pointed difference.

From the above description it will be easily seen how it was possible for the load factor of the alternating plant during the past year to have reached the high figure of 60 per cent.

There is one other feature that has yet to be explained, viz., the meter. It is obviously necessary for the consumers' meters to be of such a type as to register equally accurately with continuous as with alternate currents. This requirement,

FIG. 3.—Map of Brighton showing Streets in which Electric Light Mains are laid.

Digitized by Google

it is found, is satisfied by the modern Thomson-Houston meter. The accompanying curves (Fig. 5) demonstrate this characteristic in a striking manner.

The success of the dual system of supply to the residential outlying districts of Brighton has been such, and its working has been found so simple, that Mr. Wright (at all events, at present) is very much inclined to advise the Corporation to continue to supply Brighton at 115 volts as heretofore, rather than worry consumers with a change to the double

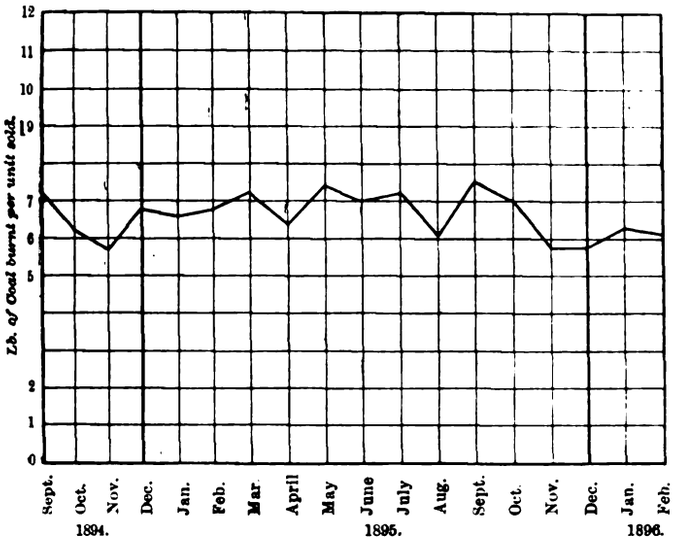

FIG. 4.—Coal Consumption Curve.

pressure, particularly as the inhabitants of Brighton have been treated to no less than four distinct systems of supply at his hands.

At present the alternating plant supplying this district consists of two E.C.C. motor alternators, having a periodicity of 70 ∿. Next year steam alternators will probably be added.

## THE THREE-PHASE SYSTEM IN SALT LAKE CITY.

In August, 1895, it became necessary to make immediate provision to increase the dynamo capacity in Salt Lake City, in order to meet the demand for lighting. A contract had been made with the Big Cottonwood Power Company for the supply of power; but there was no prospect of immediately getting this power. By this contract the Big Cottonwood Power Company have undertaken to develop a water-power in the Cottonwood Canyon, and transmit electricity over a distance of 14 miles into Salt Lake City, and there to sell the power to the Salt Lake and Ogden Gas and Electric Light Company. The Big Cottonwood Power Company will lay down a three-phase system, with a 10,000-volt transmission, stepping down at the distributing station in Salt Lake City to 2,000 volts. With these plans in view it was deemed advisable to put in three-phase dynamos at Salt Lake electric light plant, of sufficient capacity to supply the commercial centre with incandescent lights, and machinery for this purpose was purchased from the General Electric Company and erected in November last. The generating machinery consists of two 150-kilowatt and one 50-kilowatt three-phase alternators. One of the large dynamos is belted to a counter-shaft with other dynamos, and driven by a 600 H.P. Corliss engine, which runs at 100 revolutions per minute. The second is driven off the flywheel of a 250 H.P. cross-compound Armington and Sims engine, running at 230 revolutions. The third dynamo is used for the day load, and is driven off a 150 H.P. cross-compound Armington and Sims engine, together with two Edison dynamos used to supply power. All the dynamos are designed for 60 cycles. They are compound wound and have iron-clad armatures of the latest type manufactured by the General Electric Company. The 150-kilowatt dynamos are wound for an output of 2,300 volts and 37 amperes at a speed of 600 revolutions. The 50-kilowatt dynamo is wound for an output of 2,300 volts and 13 amperes at a speed of 900 revolutions. The manufacturers guarantee a commercial efficiency of 94 per cent. at full load on the large dynamos, a temperature not to exceed 70°F. above the temperature of the surrounding atmosphere after a continuous run at full load for 10 hours.

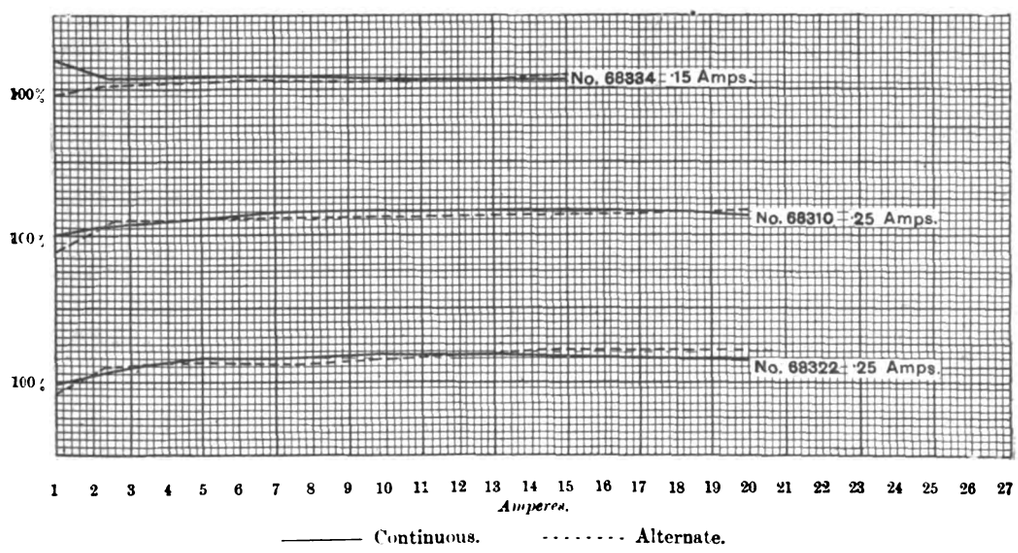

FIG. 5.—Comparative Test of Thomson-Houston Meters with Continuous and Alternate Currents. Ordinates, each division equals 1 per cent.

The length of the circuits and area of the districts can be seen from the maps. It is, of course, quite possible to work this combined system by means of pilot wires run from the central station, but as the street incandescent lamps require turning on and off, it is thought better to use that very reliable automaton the switchman. Should it ever be decided to light the streets in these residential districts by arcs, these will have to be of the alternating type, as the current is of that character during the period they are required.

There has been no opportunity of testing the dynamos for efficiency at present, but they come well within the temperature guaranteed and run absolutely sparkless at all loads.

The switchboard consists of five slabs of pink Tennessee marble, 90in. high by 30in. wide. Three of the panels contain switches for each of the three dynamos. One panel is for the measuring instruments, and the fifth panel for the circuit switches and voltmeter. At the back of the board are the 'bus-bars of the three high-tension mains, the equaliser

Digitized by Google

'bus-bars for connecting all the compound windings together, and three lightning arresters of the well-known Thomson-Houston magnetic blow-out type, with an additional protection of a flat coil of a few turns of large wire between the arrester and dynamo. Each dynamo has one transformer, which is so connected to a 'bus-bar that by throwing a small switch it can be used for lighting a pilot lamp or put in series with the other transformers for synchronising.

The effective current, as measured at full load on one wire of the dynamo, is 37 amperes upon the larger and 13 amperes upon the small dynamo. The total effective current on the three wires is about 1·73 times that on one wire, this being the ratio between the ordinates of one sine curve and the added ordinates of three sine curves at phase angles of 120deg.

On the instrument panel are three main ampere meters for registering the whole current sent out on each leg of the system, and also a Thomson three-phase wattmeter. This wattmeter is simply a modification of the ordinary Thomson meter, and consists of three separate meters, the armatures

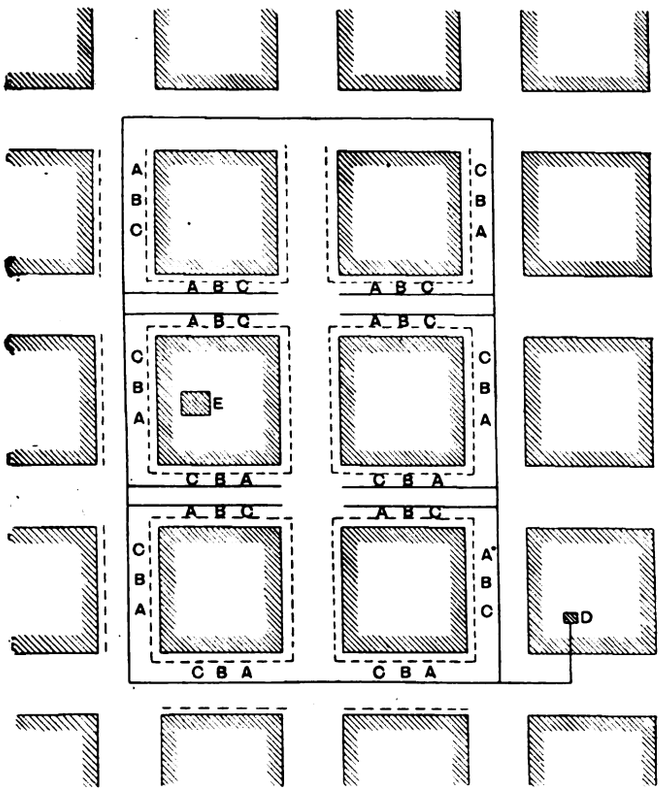

Fig. 1.—Plan of Primary and Secondary Mains in the Business District of Salt Lake City.

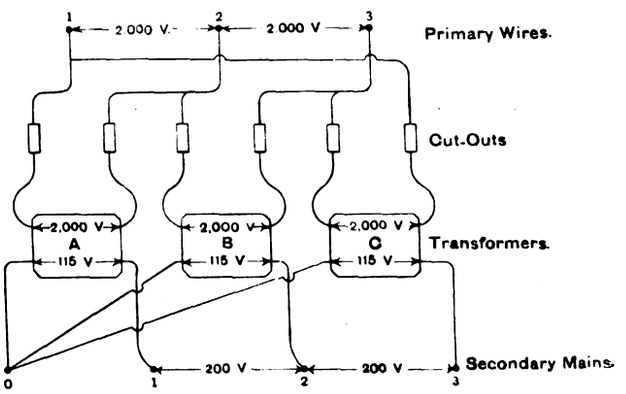
A B C, Transformers. D, New Sub-station. E, Old Electric Light Works. Full lines, 2,000 volt Three-phase Mains. Dotted lines, 115 volt Three-phase Secondaries.

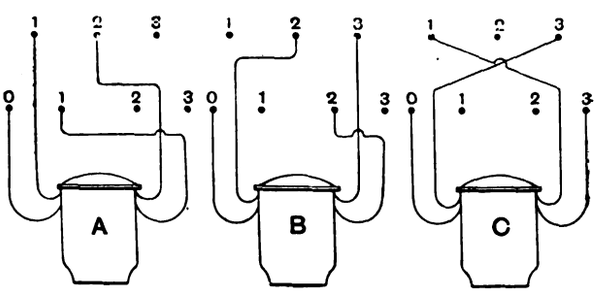
of which are all on the same spindle. In addition to these instruments a Bristol recording voltmeter is fixed in the station.

The compound commutators of the dynamos run absolutely sparklessly, and there is no trouble at all in synchronising. It may here be mentioned that the self-induction in the armatures of these dynamos is such that it is impossible to do any damage by a short circuit. Shortly after starting, a short-circuit occurred on the main lines while the small dynamo was running; the result was that the volts of the dynamo dropped off just as if the exciter switch had been suddenly opened, and, furthermore, the dynamo would not give any volts at all when running upon the short circuit. These dynamos, however, will carry 25 per cent. above their rated capacity without any loss of volts.

The distributing system consists of a three-wire high-tension network and a four-wire network of secondary mains. The accompanying plan (Fig. 1) shows how these mains are distributed over the business district. The transformers are placed upon the poles which carry the wires; the connections are made as shown in the diagram (Fig. 2). In carrying out a system like this it is, of course, important that the transformers should be fixed quickly, without any fear of getting the connections wrong. In order that the linemen may be able to make no mistake in this the wires on the poles are numbered as shown in the sketch, and the transformers are also lettered. The sketch also shows the position in which the transformers are placed in the streets, and the arrangement is such that in case of fire it would be very easy to cut off one portion of the district without interfering with the rest of the lighting. In order to save the loss in transformers during the hours of light load, arrangements are being made for cutting out a certain number of the transformers during the daytime, leaving the rest to supply the secondary mains. The transformers are wound for a ratio of 18 to 1, and it will be noticed that the secondary mains consist of a neutral wire and three others. By this means it is possible to get 115 volts between the neutral and any of the three other wires for incandescent lighting, and 200 between any two of the other wires for motor service. There is no difficulty in balancing up the three legs of the system, and, in fact, once the transformers and the secondary mains are fixed, it is easier to manipulate than an Edison three-wire system.



Transformer Connections as arranged in Banks.



Transformer Connections as arranged on Street Poles.

Fig 2

As soon as the Cottonwood power station is ready for work the preparation will be commenced for connecting the residence district on the three-phase system. At present these districts are supplied on the ordinary 1,000-volt single-phase system. A diagram (Fig. 3) is attached, which shows how the connections will be made for the three-phase. The arrangement of the streets in Salt Lake City is convenient for carrying out the necessary changes. The streets run north and south and east and west. The existing 1,000-volt mains run east and west. The three-phase feeder, as shown, will be brought up one of the streets running north and south in the centre of the residence district, and each of the cross streets will be attached to this feeder, as shown in the diagram; thus, where there are three streets, each one of the streets will form one leg of the three-phase system, and the three legs will be balanced up by throwing the side streets on to whichever leg is advisable. All the transformers at present laid down are wound for 1,000-volt primaries and 52-volt secondaries. Some

Digitized by Google

of the step-down transformers supplied by the big Cottonwood Power Company can be connected for 1,000 volts, and it is proposed to connect up the three-phase feeder to the distributing station, as shown in the diagram, at a pressure of 1,000 volts. The existing transformers would not be very efficient at 60 cycles per second, but as quickly as possible the old type transformers will be transferred to Ogden, while the new type transformers will be fixed in the residence circuits, and then, as soon as sufficient new type transformers are fixed, the voltage will be raised to 2,000, and the house lamps changed from 52 to 104.

This is an outline of the system proposed to be pursued in changing over the residence district from the existing system to the new three-phase system. It will necessarily take some time to carry out this work, but there are portions which can very easily be connected up, while it will take several months to prepare other portions of the town. In a great many parts of the residence district the houses are so close together that

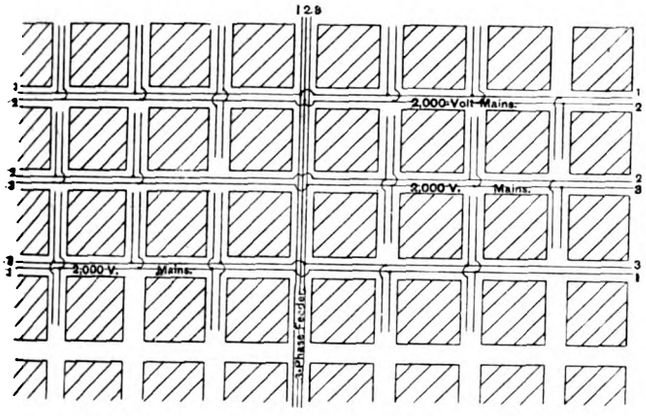


FIG. 3.—Three-Phase System of Mains in the Residential Districts of Salt Lake City.

it is very easy to fix one or two transformers to supply 10 houses. These transformers will be fixed on the street poles, and a short length of secondary main will be run, from which the houses will be supplied. At these places it is proposed to place two transformers, one, say, for 100 lights, and another for about 20, with an automatic switch to cut out the larger transformer when the number of lights does not exceed the load of the smaller, and so save the loss of power at light load.

## PROF. EWING'S PERMEABILITY BRIDGE.

Prof. Ewing's latest magnetic invention, which was exhibited for the first time at the Royal Society *soirée* on Wednesday, is appropriately described in the official catalogue as a companion instrument to the hysteresis tester which he produced a year ago (see *The Electrician*, April 25, 1895, Vol. XXXIV., p. 786). It measures magnetic permeability by a process nearly as simple as that by which the earlier instrument measures hysteresis. From the workshop point of view there is an obvious advantage in determining the **B-H** curve for a sample of iron or steel with only a fraction of the labour requisite for ballistic tests, and, it would seem, without sacrifice of exactness.

The principle of action of the new instrument is to compare the sample to be tested, step by step with a standard bar, the **B-H** curve of which has been previously determined once for all. The comparison is made by a process resembling the comparison of resistances in a Wheatstone bridge. The idea of a magnetic comparison between the piece to be tested and a standard metal is not new, having been employed in the differential magnetometer of Eickemeyer, but in Prof. Ewing's permeability bridge the idea is carried out in a very different way.

The two bars, namely, the standard whose **B-H** curve is known and the bar to be tested, are slipped into two parallel magnetising coils, and their ends are joined by two short yokes of soft iron. In Fig. 1 the bars are shown in place between the yokes, but with the coils removed. In Fig. 2 these yokes appear at the ends of the brass cover, which contains the two coils. From the yokes two long iron horns project upwards, which nearly meet above, and in the gap between these a box containing a compass needle is placed. This corresponds to the galvanometer of a Wheatstone Bridge; it serves as a detector to show when the two yokes are at the same magnetic potential, or, in other words, to show when there is no magnetic induction across from yoke to yoke through the two iron horns. Such a condition will be produced only when the magnetic induction on the two bars is the same. In that case the magnetic circuit consisting of the two bars and the yokes will be complete in itself. The lines that go from right to left along one bar will all return from left to right along the other. The yokes will be at the same magnetic potential; the horns will remain unmagnetised and the detector will not deflect. If both bars have the same perme-

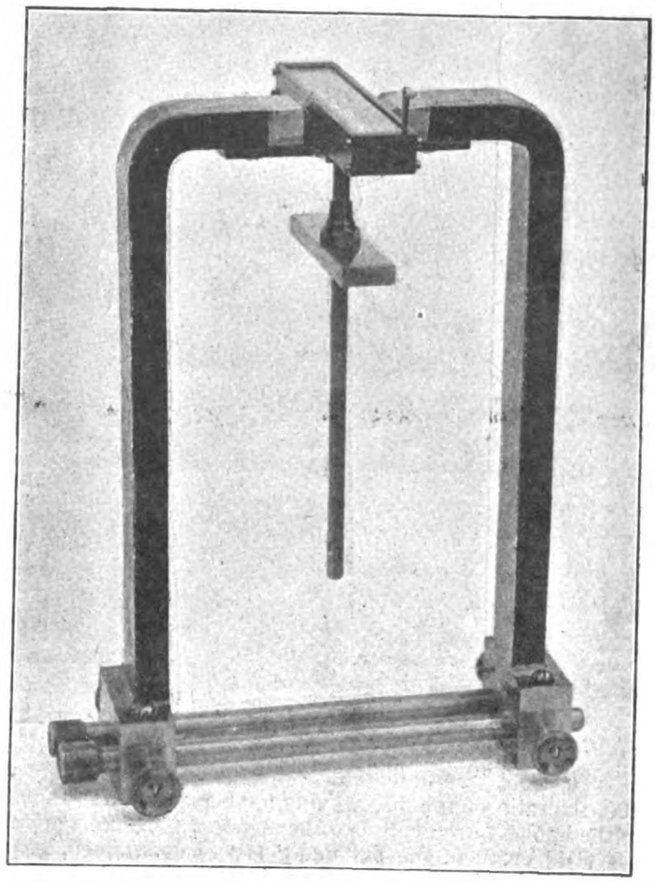

FIG. 1.—Bars, Yokes and Horns: cover removed.

ability this state of balance will be produced by having the same number of ampere-turns act on each; but if they differ in quality the condition of balance can still be produced by altering the relative number of ampere-turns. To do this the number of effective turns in the magnetising coil of the sample bar is altered by means of the dial switches, while the same current passes through both coils.

To get rid of all effects of hysteresis in the bars, and in the yokes and horns, a reversing key (shown on the right) is worked while the adjustment proceeds, and the balance is perfect when each reversal produces no permanent displacement of the compass needle between the horns. A transient kick will even then in general be observed, owing to a difference in the time-rate with which the two bars take up their magnetism. In practice the adjustment by means of the dial switches is very readily made, and takes no longer than the corresponding process in measuring resistances. To prevent the current from altering while it is going on, the switches are furnished with a second set of contacts which throw in

Digitized by Google

compensating resistances as the number of turns in the magnetising coil is reduced, with the effect that the total resistance of the circuit remains unchanged. The clear length of each bar is 12·56cm. ($4\pi$), and the number of turns in the magnetising coil of the standard bar is 100. Hence, the magnetising force due to its coil is 10 C.G.S. units for each ampere of current. This allows any required magnetising force to be easily applied, with the aid of an ampere meter and an adjustable resistance outside the instrument. Further, since the relation of **B** to **H** is known for the standard bar, a knowledge of the current is enough to show at what value of the induction **B** the comparison is being made, and **B** is, of course, the same for both bars when the condition of balance is produced. The number of turns on the other bar then gives, by its ratio to 100, the ratio of the magnetising force required for that bar to the known force applied to the standard. Hence a point in the **B**-**H** curve of the bar under test is determined, and by changing the current as many points as are wished may be found. In practice it appears to be most convenient to bring the current to a value such as 1 ampere, and then increase it by similar steps, thus making **H** take values of 10, 20, &c., successively.

The detector is more than sensitive enough to show the effect of one turn more or fewer in the magnetising coil when the state of balance is approached, and might even be used, by interpolation between the deflections to right and left, to estimate the fraction of a turn necessary for exact balance, although in practically carrying out magnetic tests this would be superfluous.

We are informed by Prof. Ewing that he has for some months used the new bridge in his own tests, and that, apart from its great convenience over the ballistic method, he finds it actually a more delicate means of detecting difference between one sample and another. The absolute values are, of course, dependent on the primary measurement of the standard bar, which is made ballistically.

The dial switches in the instrument exhibited give the means of increasing the number of turns on the test-piece up to 210. In cases where the test-piece is magnetically much worse than the standard, a ratio of rather more than 2 to 1 may be insufficient; and to provide for that there is a two-way arrangement, by which the number of turns on the standard bar is readily reduced to 50, when **H**, of course, becomes 5 instead of 10 per ampere, and the sample under examination can then have more than four times as much magnetising force as the standard bar.

When it is desired to test the permeability of sheet metal the samples are formed by piling up a number of straight strips, giving a total cross-section equal to that of the standard, and a different form of yokes is employed. In the arrangement used with bars, which is shown in the above figures, the attachment of the bars to the yokes is of the simplest possible kind; the bars slip through holes in which they are a loose fit, and they are pressed against the middle portion of the yokes by a pair of set screws outside. The effective contact between bar and yoke, therefore, is made in the place best adapted for shortening the magnetic circuit through the yokes.

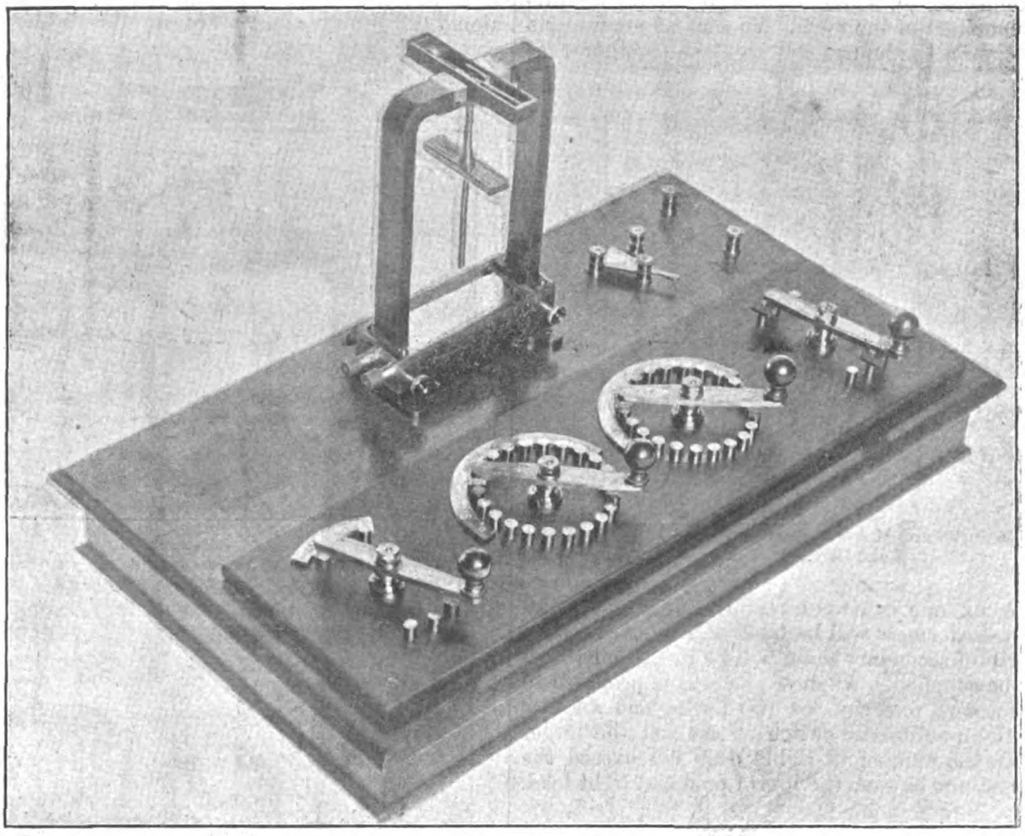

Fig. 2.—General View of Apparatus.

## PUBLIC LIGHTING BY ARC LAMPS.*

BY ANDRÉ BLONDEL.

*(Concluded from page 18.)*

### III.—USE OF ALTERNATING-CURRENT ARCS.

So far there have been very few towns lighted by alternating-current arcs, for the reason that the most important localities have generally been so long furnished with continuous-current supply stations or with special methods for series arc lighting; but as alternating-current supply stations have multiplied rapidly of late the question of the use of the alternating-current arc for public lighting comes up for solution. I shall, therefore, investigate the most suitable means of utilising this source of light, and then compare it with the continuous-current arc. The results of my preceding investigations will enable us to complete this comparison very readily.

*Strength of Current and Size of Carbons.*—It is important to note that for an equal number of watts an alternating arc requires a much

* From *La Rêtue Technique*. Translated by Mr. John Hesketh.

Digitized by Google

lower voltage than a continuous-current arc—28 to 32 volts instead of 45, and consequently an increased current.[56] One may generally assume that for equal power one and a-half times more current is needed with the alternating than with the continuous-current arc, and therefore we are led to the use of 10, 15, and even 20-ampere lamps. This again necessitates the use of larger conductors and carbons of a much larger diameter, which latter are not favourable to luminous efficiency. Instead of increasing the current, it would in most cases be found advantageous to adhere to the maximum value of 10 amperes, and to increase the number of arcs, taking advantage of the lower voltage. For instance, on a circuit of 120 volts, four 10-ampere alternating arcs may be placed; while only two continuous-current arcs could be used. From the point of view of the greater division of the light this is an advantage. Public lighting by continuous and by alternating currents should not therefore be carried out in exactly the same manner. In the case of alternating arcs a greater number of lamps may be used, and these may be fixed closer together.[57] As an alternating-current arc taking 10 amperes is equivalent, as far as wattage is concerned, to a continuous-current arc taking about 7 amperes, there is no need really to endeavour to bring smaller current lamps into use. Besides this, small current alternating arc lamps have the additional inconvenience of a decreased stability

*Helios Alternating Arc Lamps.*

| Current. | Carbons. | | Hours carbons burn. |
|---|---|---|---|
| | Diameter. | Length. | |
| 8 | 10mm. | 320mm. | 14 to 15 |
| 10 | 12mm. | 320mm. | 14 to 15 |
| 16 | 15mm. | 320mm. | 14 to 15 |
| 20 | 18mm. | 320mm. | 14 to 15 |
| 30 | 20mm. | 320mm. | 14 to 15 |

*Details of Alternating Arcs used in Public Lighting.*

| Town. | Current. | Volts. | | Diameter of carbon. |
|---|---|---|---|---|
| | | At terminals. | Total. | |
| Havre (Brianne lamp) | 12 | ... | 36 | 12mm. and 14mm. |
| Clermont-Ferrand... (Brianne lamp) ..... | 12 | 26-28 | 33 | 12mm. |
| | 20 | 26-28 | 33 | 20mm. |
| Cologne (Helois lamp) | 30 | 29 | 36 | 20mm., 320mm. long |

All these diameters are proportionately less than those I have given previously for continuous-current arcs, and it appears as-

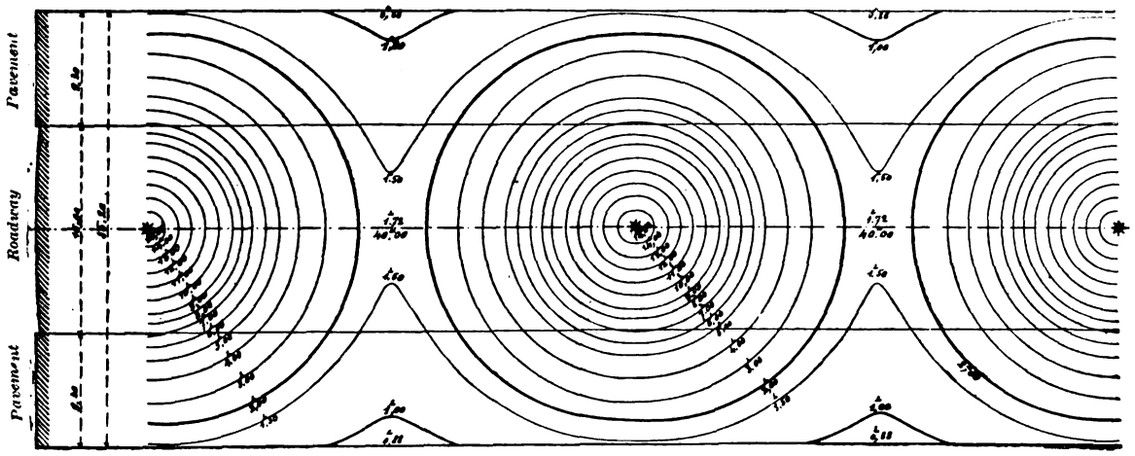

FIG. 59.—Plan of Illumination of the Grand Boulevards, Paris, with 10-Ampere Continuous-current Arcs and Opaline Globes, 6m. high, and on Refuges in the Centre of the Roadway.

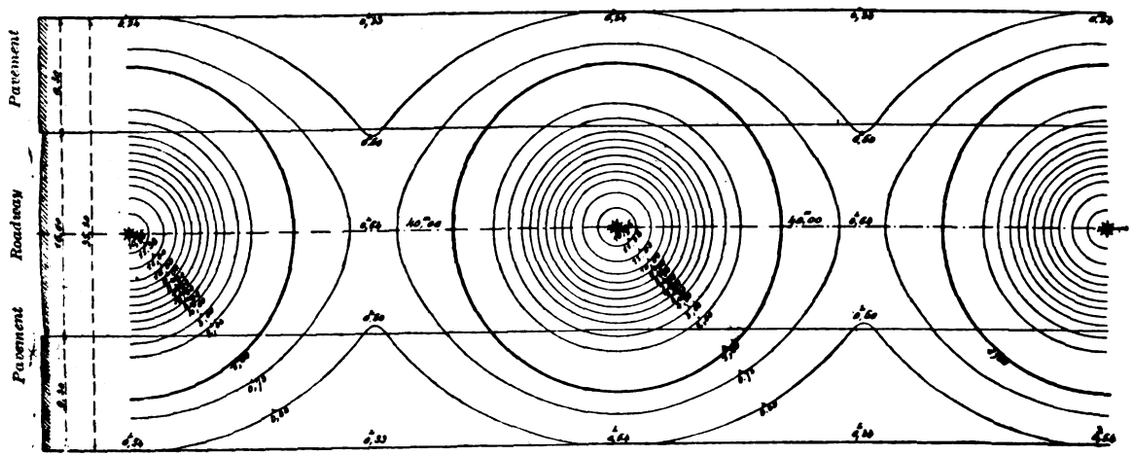

FIG. 60—Plan of Illumination of the Grand Boulevards, Paris, with 10 Ampere Continuous-current Arcs and Holophane Globes, 6m. high, and on Refuges in the Centre of the Roadway.

and a greatly reduced luminous efficiency, two points to which we have already called attention.[58] As examples of public lighting by alternating-current arcs we may cite Havre, Clermont-Ferrand and Cologne. The following are details as to the diameter of the carbons and the currents in use[59]:—

though it might be wise to still further reduce them, using specially adapted globes, or double-carbon lamps, for the same reasons as given in the case of continuous-current arcs. No practical trials have as yet been made in this direction for public lighting. It must not be forgotten that in French electric lighthouses incomparably superior luminous efficiencies were obtained with the alternating currents by the use of higher current densities in the carbons, 2½ amperes per square millimetre being adopted.

*Distribution of the Rays.*—The two carbons are equally consumed, and gradually shape themselves to a conical point terminated by a facet. In consequence of this, the photometric curve of the naked alternating arc has the characteristic form of two butterfly wings with a point of recess. I have elsewhere given the reason for this form.[60] It is sufficient here to say that it is approximately symme-

[56] We shall see later that the number of true watts is really lower than the product of the amperes into the volts; but as this difference is small in actual practice I shall neglect it, although it may be assumed that this involves an actual increase of 5 per cent. to 10 per cent. in the current.

[57] For the lighting of the railway stations at Dresden another equally practical system has been adopted; which is, to distribute at 70 volts, so that incandescent lamps at 70 volts, or two arc lamps in series at 35 volts, (of the Helios pattern) can be used.

[58] *La Lumière Electrique*, October, 1894.

[59] For these we are indebted to MM. Berthier, Coerper and Dalichampt.

[60] *Eclairage Electrique*, May, 1895.

Digitized by Google

trical on either side of the horizontal. The upper half is, however, generally, most fully developed because of the more pointed shape of the upper carbon. Under these conditions we see that at least half of the luminous flux is sent upwards, while the rest is distributed on the ground following a law very slightly different from that applying to continuous-current arcs.

*Effect of Diffusing Globes.*—The effect of globes does not alter the symmetry of the curve if the arc is placed in the centre, and consequently the total flux on leaving the globe divides itself into two approximately equal parts, of which one is sent upwards and the other downwards. In addition, the curves are distorted in such a manner as to make them incline towards a circular form more readily than is the case with continuous-current arcs. Figs.

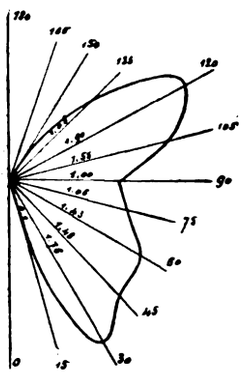

FIG. 61.

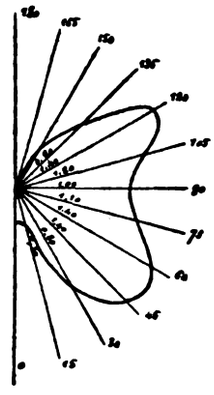

FIG. 62.

61, 62, and 63, for example, give the curves which I have obtained experimentally from a lamp, first with a naked arc, then with opaline and opal globes. In these curves the horizontal intensity has been taken as unity in every case, so that the different curves must not be compared with each other[61]. The comparisons are besides very easy to make without this. For the total loss of light corresponds to that due to absorption only, and the lower hemispherical flux is sensibly the half of the total flux, both before and after this absorption. The figures given previously as to the

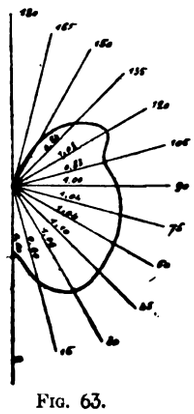

FIG. 63.

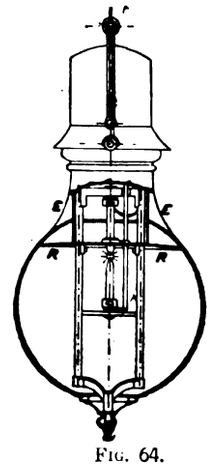

FIG. 64.

absorption with continuous-current arcs enable us to determine the luminous efficiency in the following manner, if we take the flux produced as unity.

| — | Flux produced. | Total flux after absorption. | Hemispherical flux. | Efficiency. |
|---|---|---|---|---|
| Arc under rough glass globe | 1 | 0·69 | 0·345 | 0·345 |
| „ opal „ | 1 | 0·55 | 0·275 | 0·275 |

I cannot give the results with the holophane globe because it has not yet been tried under these conditions and is not comparable with the others by this method. Even with clear opal globes a higher efficiency than 40 per cent. cannot be hoped for. The low efficiency obtained shows that it is a mistake to endeavour to use the alternating-current arcs in the same way as continuous-current arcs, as has been done in France, where alternating-current arcs have been placed in lanterns exactly similar to those used for continuous-current arcs. So long as we consider the lighting of narrow streets we may still consider that a part of the light sent upwards is returned to us by the diffusing effect of the house frontages, but this no longer holds on boulevards which are at all wide. It is still worse when such an arrangement is used along a marine promenade as has recently been done, for instance, at Hastings. Under these conditions, scarcely a third or fourth of the light is utilised. The use of the alternating-current arc does not appear to be rational unless a special equipment of reflectors or a dioptric arrangement is employed.

*Use of Reflectors.*—For a reflector to be satisfactory in actual use its solid angle should be as near as possible a hemisphere. We have previously seen that it is scarcely possible to obtain these conditions with a reflector outside the globe unless we use arrangements which are very ugly and cumbersome, and which are in addition difficult to keep clean. It is far preferable to place the reflectors in the interior of the globe and quite close to the arc. Such was the solution suggested a little while ago by the Helios Company of Cologne. Fig. 64 gives a view of the latest pattern of the lamp constructed by this Company, and one which has been employed with success in the public lighting of the streets of Cologne.[62] A reflector of enamelled iron is fixed to the guide rods. The lamp being of the focussing type, the arc always remains in immediate proximity to the reflector which embraces a solid angle of almost $2\pi$. These conditions are the most perfect for the reflection of the light otherwise sent upwards.

In Fig. 65 we have the result of experiments made by the Helios Company, and also give the curves obtained with and without the small reflector. The curves are for a lamp of 10 amperes taking 310 watts. It will be seen that the distribution of the rays in the lower hemisphere follows approximately the same law

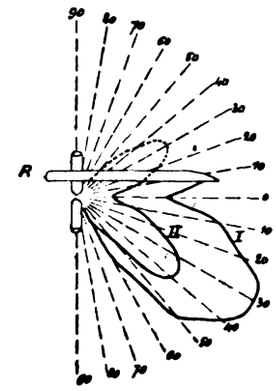

FIG. 65.

in both cases, with the difference that the intensities are almost doubled by the use of the reflectors. The hemispherical intensity is increased from 150 to 372 candles. The mean intensities deduced from these curves are: without reflector 275 spherical candles, without reflector 498 hemispherical candles, for 310 watts, which gives 1·6 candles per watt. The corresponding fluxes are: $4\pi \times 275$, and $2\pi \times 498$ units. The second figure is certainly exaggerated. To prove that this is so it is sufficient to point out that the total flux $4\pi \times 275$ is the sum of the upper hemispherical flux (equal to about $2\pi \times 250$ according to the curve) and of the lower hemispherical flux (equal to about $2\pi \times 300$). The lower flux is thus increased from $2\pi \times 300$ to $2\pi \times 498$ units; and consequently the reflecting power of the small reflector must have a value of

$$\frac{250}{498-300}=\frac{250}{198},$$

that is to say, it is greater than unity. As a matter of fact, it does not appear that a diffuser of this kind can reflect by diffusion more than 70 or 80 per cent. of the light it receives. Assuming that the light of the alternating-current arc is divided into two equal parts, the one above and the other below the horizontal, the luminous efficiency of the lamp with its reflector would be 85 to 90 per cent., which is indeed very good. This light has still, however, to submit to the same losses as those to which the continuous-current arc is subject by the action of the diffusing globe which encircles the arc; but still the small reflector will at least allow us to obtain an increase of light of 70 to 80 per cent. above that obtained from a lamp not so fitted.

In the face of such a result one can but wish to see this arrangement employed in France, where, so far, the use of the light of the

[61] I have, indeed, made a comparison between their intensities on a horizontal plane, but in consequence of the variations of intensity, the result was not sufficiently accurate to warrant me in reproducing it here.

[62] The previous pattern employed only half a globe, covered by the reflector, an arrangement which was scarcely graceful. The present type is much more satisfactory for use in places where some elegance can hardly be dispensed with.

Digitized by Google

alternating-current arc has not been properly understood, and where few engineers seem to trouble themselves about the question. The small Helios reflector presents a great additional advantage in not requiring any modification in the ordinary fittings; and externally a lamp so fitted cannot be distinguished from any other unless it is by its greater lighting power.

*Use of Dioptric Globes.*—The holophane dioptric apparatus previously mentioned will also give a good solution to the question; in fact, better from many points of view than the preceding one, but it has not yet been practically tried. It is true that the holophane globe as applied for continuous current could not be applied to alternating arcs, for the arc is so near the top opening that all the light sent upwards would be lost through the opening[63]; this inconvenience could, however, be easily overcome by arranging the lamp rods so as to carry a small reflector above the opening, which shall reflect all the rays which would otherwise pass through.

Another device which appears still more advantageous consists in using a special globe, at the centre of which the luminous point is fixed, the ribs of the globe being so arranged that they direct all the rays towards the ground. This arrangement would appear to be the most perfect for use with alternating-current arcs, but it must not be forgotten that if long carbons are to be used the bottom carbon holder must pass through the bottom of the globe.

*Comparison between Continuous and Alternating-Current Arcs from the Point of View of Luminous Efficiency.*—Now that we have seen what proportion of the light emitted by the alternating-current arc can be used by the aid of dioptric fittings, it is natural to ask whether, since we can conveniently use this light, it is equivalent to the continuous-current arc from the point of view of utilisation of energy. So far the experiments seem to establish that for equal energy consumed the alternating-current arc produces less luminous flux than the other. This is easily explained when we remember that for every alternation the arc really goes out for a greater or less time and is then relighted. During its extinction there is a sensible cooling of the incandescent portion of the carbon, for at these very high temperatures radiation is considerable. Besides which each of the carbons is positive, and therefore raised to its maximum luminosity only during one alternation out of two; and when it is negative its brilliancy is much less.[64] It, therefore, must result that in the alternating arc the mean degree of incandescence, and consequently the luminous output (which varies as the temperature), is much lower than with the continuous-current arc taking the same energy, and that the difference will increase the longer the extinctions. I gave many years ago* this *a priori* demonstration of the difference in the efficiency of the two kinds of arc; and I hope it may be true, though such eminent authorities as Prof. S. P. Thompson think the luminous efficiency depends only on the watts in the arc, and must necessarily be the same when the watts are the same. Among other consequences we have the result that the more powerful arcs have a better efficiency than the smaller ones, and the efficiency increases a little with the frequency of the alternations. It should also be noted that the incandescent portions of the carbons in the alternating-current arc are more eclipsed than in the case of continuous-current arc, and that we have consequently a very appreciable loss of light. This fact is the more important, since for equal power an alternating-current arc requires, as we have seen, larger conductors and larger carbons than a continuous-current arc.

As to establishing what is the relation between the luminous efficiency of continuous and alternating-current arcs, this is a point still very imperfectly settled, owing as much to causes of variation which I will mention as to the imperfect methods by which measurements have been made.

Before quoting figures on this subject I may make the remark that the alternating-current arc may present altogether different properties, according to the nature of the carbons employed, and that the comparison is difficult to establish on a precise basis.

With the homogeneous carbons hitherto used, the voltage at the terminals is 35 to 40 volts, and the power factor very small—that is to say, for a given number of true watts in the arc the apparent watts supplied (*i.e.*, the product of the current into the difference of potential) is appreciably higher. The power factor of the arc sometimes is as low as 0·7 or 0·8. In addition to this arcs taking less than 12 amperes are very unstable[65]. With carbons as used at present, with the core formed of highly conducting material, the voltage required is much lower and may even be as low as 28 or 30 volts (with the Helios lamps.) The power factor may reach 0·95 to 1—that is to say, the apparent watts differ very slightly from the true watts. In addition, the stability is so good as to almost enable one to dispense with impedance coils in the circuit. All these advantages are due to the artificial conductivity of the arc due to the vapourisation of the salts contained in the core, but we must nevertheless notice that this is probably obtained at the expense of the luminous efficiency, for this conductivity is opposed to the attainment of the same brilliant incandescence as in previous arcs.

The alternating-current arc lamp of the Helios Company, which at the present moment is the most prominent type, really presents a phenomenon intermediate between constant incandescence and the phenomenon of the arc properly so called. The luminous efficiency should also be intermediate, and in consequence lower than that of the continuous-current arc.

From measurements made by Prof. Fleming on arcs taking 540 watts[66] the ratio of the efficiency is about 2 : 3. This figure is lower than that arrived at by the Frankfort Commission, which was 4 : 5. Assuming that this figure may be accepted as an average, the flux of light sent downwards for public lighting would be, for equal power, only one-third of that of the continuous-current arc, if a reflector is not employed, and 1·70·3, that is to say, about one-half if a reflector with 0·70 reflecting power be employed. If we may rely upon the recent experiments of Herren Wedding and Roessler, this figure is even then too favourable. By directly measuring the light from a Helios lamp fitted with its reflector and taking 9 to 10 amperes at 25 to 31 volts (about 280 true watts) they found a mean return of 0·7 to 1·1 Hefner unit[67] (mean spherical) per watt, whilst a continuous-current lamp taking the same power (6 to 8 amperes) gave 2·64 units per watt.[68] These figures are confirmed by some recently published by Herr Görges,[69] which indicate about 0·8 to 0·96 Hefner units per watt according to the type of alternator. The ratio of utilisation is thus only 1, 2·64.

The figures given by the Helios Company are much more favourable. I should, however, remark that they apply to more powerful lamps, and that the figure of 2·64 quoted here was obtained with carbons of such small diameter that they could not practically be used. With ordinary carbons only 1 to 1·5 candles per watt can be obtained.

In the face of these very great divergencies we are obliged to admit that experimentally, as well as theoretically, the alternating-current arc has a lower efficiency, and to await special experiments to define the exact ratio. I hope some day to publish results on this point, obtained by the aid of my lumen meter.

*Indirect Ways of Avoiding the Use of Alternating-Current Arcs for Public Lighting.*—Up to the present engineers have, as a rule, avoided the difficulties of the use of the alternating-current arcs

* *Loco citato.*

[63] This really takes place in the globes at present in use. Lampmakers—careful above all things to keep the carbon holders within the globe—almost always place the arc high up in the globe, and since the globe is closed at the top by a non-reflecting surface, half the light is inexcusably lost. This is a beautiful example of the absurdities current in questions of lighting.

[64] A complete study of these phenomena was published by the author in *La Lumière Electrique*, December, 1891, and January, 1892.

[65] For fuller details on this point, see *La Lumière Electrique*, October, 1893

[66] Dr. Fleming found in red light 342 and 217 mean spherical candles, and in green light 646 and 407 (see *Lightning*, October 25, 1894). Since these lines were written another Paper has been published (see *The Electrician*, December 20th, 1895), by Prof. Fleming and M. Petavel, in which they give more information on the subject. According to this most valuable contribution to the study of the alternate current arc, the efficiency of this arc would be about 0·5 mean spherical candle (0·65 pyr), instead of 1 to 1·25 candle (1·3 to 1·62 pyr), as for the continuous current arc. Although the experiments referred to may be not exactly comparable because the lengths of the arc varied between too large limits (0 to 8mm), the results must be relied upon as clearly showing the inferiority of the alternate current arc with low voltage carbons, and giving a confirmation of the measurements of Görges and Wedding alluded to here. The periodic curves of current and P.D. of Prof. Fleming and M. Petavel are also a confirmation of one particular form amongst the many forms I published three years ago; I had already drawn attention, though not so well, in another paper (*La Lumière Electrique*, 1891, Vol. 42, p. 618), to the fact that the brightness of the crater on the carbons is periodically variable, and some of my photographs (*La Lumière Electrique*, Vol. 43, p. 57, No. 25), show its variations during the period with the two unequal maxima, of which the causes are evident. I must add that the light attributed to the arc when the current passes through zero is more probably produced not by the arc but by the *flame* that surrounds it, and comes from the burning carbons. The method of the synchronously rotating disc for observing the carbons and arc was originally indicated by Prof. Joubert five years ago, if not in 1881.

[67] The Hefner unit is 1·04 pyr, or *bougie décimale*.

[68] Herren Roessler and Wedding have laid great stress upon the fact that with machines giving electromotive force curves of another shape, the efficiency might be even still further reduced. This is not surprising, and I long ago pointed out that the duration of the extinction of the arc, and in consequence its mean degree of incandescence, may vary very much according to the constitution, not only of the alternators, but also of the circuit. However, in actual practice the different types of alternators only give rise to very slight differences. If the authors we have quoted found very great variations, it is because they used antiquated types of alternators under conditions which are not generally met with in the distribution of energy. Their conclusions ought therefore to be accepted with a certain reserve. I may note that their mean figure is in every case very much lower than the one I have quoted.

[69] *The Electrician*, December 13, 1895, p. 230.

by putting down special mains to be supplied with continuous currents for public lighting, even in towns supplied on the alternating-current system. This tendency has been assisted by the fact that special types of arc lighting machines exist (Brush, Thomson-Houston, &c.), and by the preference so long given to series distribution for arc lighting. Therefore, in many towns a special station has been erected or special machines have been fixed in the urban station for arc lighting. But this system has many inconveniences, of which the most important is that it calls for the use of special plant, which is always expensive, and thereby reduces the coefficient of possible use of the principal part of the station. In France we labour under the disadvantage that the use of high pressure along public thoroughfares is not readily permitted, and the series system, which calls for relatively much greater precautions, has therefore fallen more into disfavour. Again, this system does not easily allow of the use of lamps of varying candle-power. It is almost always easier, and quite as efficient, to connect public lamps to the general system of distribution. This arrangement will soon be the only one in use in Paris and in almost all the towns in France. Even in America, the Fatherland of series arc lighting, it has found favour. The beautiful lighting of the Fifth Avenue at New York, for instance, is done by lamps arranged two in series across each side branch of the Edison network. We ought, then, in the same manner to try and use the existing alternating-current mains on account of simplicity and of the load factor. From what we have already seen, to simply place alternating-current arcs on the secondary network—even if this secondary network is a special one—as is done at Havre and Clermont, is a bad solution which can only be improved by the use of special optical arrangements.

Many engineers propose to attain the same advantages by a different method, namely, by eliminating the alternating arc without giving up alternating currents. An important and very interesting development has recently taken place in England, due to Mr. Ferranti, who uses an apparatus called a "rectifier." The alternating current at high pressure and constant voltage is first transformed into an alternating constant-current and varying voltage, such as is required for series arc lighting. This is done by the aid of specially constructed transformers, with a movable secondary circuit. This secondary is repelled or attracted by the primary in such a way as to render the current constant, at the same time as it maintains the electromotive force proportionate to the number of lamps in circuit. This secondary current before being sent into the distribution network passes through a revolving commutator, similar to the old Clarke commutator, revolved by a small synchronous motor, and on which the brushes are so set that the alternating current is commuted at the moment when it is at zero. The result is that a current always in the same direction, but pulsating, is obtained for feeding the arcs. The arcs formed are then practically the same as for continuous currents. A crater is formed on one only of the two carbons and produces the greater portion of light. By making this the top carbon the same distribution of light is obtained as with a continuous current. A point in favour of this system is that, owing to the constant vibration due to the pulsating current, the feed of the carbons is much more regular and even than with constant currents. Installations for public lighting on this system have been carried out at Portsmouth, Cardiff, and Blackpool, where very satisfactory results have been obtained. In reality this system is not so novel as would first appear, for the first electrical machines which were ever constructed—Alliance and Holmes's—were alternators fitted with rectifiers, and the arcs supplied by them in lighthouses where they were used were pulsating arcs. This rectifier was promptly discarded in favour of the alternating arc pure and simple, because of the rapid deterioration of the commutator by reason of the sparking. It must be thought that the Ferranti rectifier will not have the same defect, thought it is very difficult to commute currents in circuits with self-induction without very strong sparking. Unfortuneately, it is quite possible that the luminous efficiency of such arcs will be somewhat less than that of a pure continuous-current arc, for it is liable to short extinctions at each alternation. Two other objections may also be made to this system. One is the low efficiency of the special transformer employed, and the other is the danger resulting from the use of commutators at such high pressure where one has to regulate the brushes by hand. Apart from danger of shock, pulsating currents being about as dangerous as alternating currents, it is to be feared that the least irregularity in the line of commutation will give rise to rather serious arcing. For these reasons it appears to me still preferable to convert alternating currents from high or low tension into continuous currents at constant potential for distribution in parallel. This transformation is easy in the case of a network fed by polyphase currents where rotary transformers of the Lahmeyer or similar type can be employed. To make this transformation possible for simple alternating currents, the author devised a special rotary transformer, which may be useful for public lighting in the numerous towns where distribution is carried out by single-phase alternating currents. The efficiency of this transformer complete is expected to be 87 per cent. to 90 per cent. according to the size, which enables a much greater quantity of light to be obtained with the same amount of energy than could be obtained by the direct use of alternating currents. The solution possesses the advantage of absolute security, and allows lamps which have already been long tried in lighting with continuous currents to be used. The troubles of alternating currents in the regulation of the lamps are avoided. It must be remembered that the properties of these currents are variable according to the form of the curve of the electromotive force of the machine. A lamp which will work well in the factory may do no such thing when placed in service on the network. Nothing of the kind is to be feared with the continuous current.

### Conclusions.

I have shown in this investigation that the question of utilisation of the light of arc lamps is a complex one, and that we are far from having reached a definite solution. Lamps are almost always fitted with carbons of too large a size and too short a travel. Bad globes are very often selected—either they do not temper the brilliance of the arc sufficiently, or they absorb too much light. Finally, we are still not sufficiently advanced for

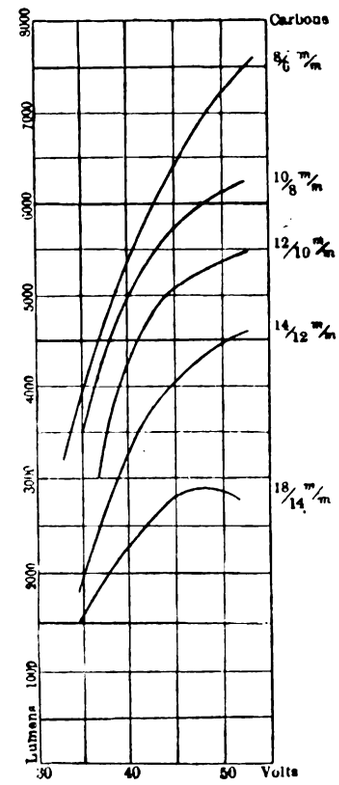

Fig. 66.

the rational use of the alternating arc, though holophane globes and small interior reflectors constitute very important steps forward. There are, nevertheless, many things to be done before we obtain the best luminous efficiency for the energy consumed. One of the most important desiderata is the construction of a good focussing lamp, with multiple carbons, and of such a design as to admit of the use of carbons of greater length. The photometric value of alternating arcs is still very doubtful, but it certainly appears to be mediocre, and it would seem well to replace them by pulsating or continuous-current arcs when possible. I wish these remarks to lead engineers to study the various and interesting problems which public lighting affords, and I hope they will create in them a desire to make really useful progress.

### Appendix I.

During the publication of this work I have, with the assistance of MM. Laporte Coster and Revel, taken at the Central Laboratory a series of measurements of the flux of 10-ampere continuous-current arcs under various conditions. The curves (Fig. 66) here given show the first results attained, and confirm the generalisations made in the first portion of this article. Each curve corresponds to a pair of carbons of the size shown. The abscissæ give the voltage at the carbon points and the ordinates the flux in lumens. (The mean spherical intensity in candles is this figure divided by $4\pi$.) By comparing the number of watts with the number of lumens we

I am indebted for these data to the courtesy of Messrs. Monmerqué, Quintin, de Joukowsky, C. Cervi, Vermehren, Kirschner, Rothenbach, Uppenborn, J. Christie, W. Arnot, McCormick, J. P. Barrett, J. Harper, Février, Dalichampt, Joly, John Hesketh, H. Faraday Proctor, A. W. Ranken and E. Price.

have a measure of the efficiency. This is a maximum at about 45 volts for the kind of carbons employed. The carbons were furnished for these experiments by the Société de Nanterre, and were of excellent quality. The lamps placed at our disposal by M. Bardon worked with remarkable precision. Thanks to these two favourable factors, we have been able to obtain figures which may be relied upon provisorily, excepting as regards the larger carbons (18mm. and 14mm.), where the arc varied somewhat, and the results are less certain.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**(To-day) FRIDAY, May 8th.**

IRON AND STEEL INSTITUTE.

*10:30 a.m.* General Meeting at 25, Great George-street, S.W. Various Papers to be read and discussed.

KING'S COLLEGE ENGINEERING SOCIETY.

*4:15 p.m.* Meeting at King's College, Strand. Presidential Address by Magnus Mowat on "Horseless Carriages."

PHYSICAL SOCIETY.

*5 p.m.* Meeting at Burlington House. Papers to be read: (1) "On Dielectrics," by R. Appleyard; (2) "On the True Resistance of the Electric Arc," by Messrs. J. Frith and Rodgers.

INSTITUTION OF ELECTRICAL ENGINEERS.

*8 p.m.* Students' Meeting at 28, Victoria-street, S.W. Paper to be read: "Single-Phase Alternate-Current Transformers in Practice," by A. F. Berry.

INSTITUTION OF JUNIOR ENGINEERS.

*8 p.m.* Meeting at the Westminster Palace Hotel. Paper to be read and discussed: "Notes on Belgian Electrical Engineering Practice," by A. Anstruther-Thomson and G. C. Allingham.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Electric Shadows and Luminescence," by Prof. Silvanus P. Thompson, F.R.S.

**SATURDAY, May 9th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

Students' visit to the London Electric Supply Corporation's Station at Stowage Wharf, Deptford.

**MONDAY, May 11th.**

SOCIETY OF ARTS.

*8 p.m.* Cantor Lecture III.: "Applied Electro-Chemistry," by James Swinburne.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

*8 p.m.* Meeting at the Palatine Hotel, Hunt's Bank, Manchester. Paper to be read: "The Use and Economies of Rectifiers for Arc Lighting," by John Hesketh.

**TUESDAY, May 12th.**

ROYAL INSTITUTION.

*3 p.m.* Afternoon Lecture (II.): "Ripples in Air and Water," by C. Vernon Boys.

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Ordinary Meeting. Papers to be further discussed: (1) "American and English Methods of Manufacturing Steel Plates," by Jeremiah Head; (2) "Four American Rolling Mills," by Samuel T. Wellman.

**WEDNESDAY, May 13th.**

SOCIETY OF ARTS.

*8 p.m.* Ordinary Meeting. Paper to be read: "Tunnelling by Compressed Air," by E. W. Moir.

**THURSDAY, May 14th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*8 p.m.* Ordinary General Meeting. Paper to be read: "The Influence of the Shape of the Applied Potential Difference Wave on the Iron Losses in Transformers," by Stanley Beeton, C. Percy Taylor and J. M. Barr.

**FRIDAY, May 15th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*5 p.m.* Students' visit to the Robertson Incandescent Lamp Factory, Brook Green, Hammersmith.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Cable Laying on the Amazon River," by Alexander Siemens.

*** Particulars of Meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p m.

**Electric Power for the Hogback Tunnel, Colorado.**—This tunnel, which is to form a portion of the new waterworks system of Colorado springs, is to be 6,400ft. long and will be constructed from both ends. The air-compressors are to be run by a 75 H.P. three-phase motor. The generating station is to be erected a short distance above the Iron Springs Hotel, at Manitou, and the water necessary for the generation of the electric current is to be taken from the pipe line which now supplies Colorado Springs with water, and after being used for this purpose will be again conducted to the pipe line. The water has a fall at the site of the power station of 700ft. The power is to be generated by a 150 kilowatt 3,600-volt three-phase generator. The current will be transmitted about eight miles, and will be used to run the air-compressors, supplying lights and for other necessary purposes.

## RECEIVERS IN BANKRUPTCY.

Although it is our custom to regularly report all legal cases affecting the interests of the electrical industry, we rarely feel called upon to make any comment upon them from a purely legal aspect. The maxim that a cobbler should stick to his last is indeed a very excellent one, and in transgressing it by the remarks we propose to make on the case of "GASKELL *v.* GOSLING," which was briefly reported in a recent issue, we do so in the full consciousness both of the enormity of the offence and of the fact that it will be condoned by those who have had the misfortune to be "taken in" by our bankruptcy laws. Of course there are superior persons who have never been entrapped by deceptive appearances into contracting a bad debt, and others whose calling in life renders it unlikely that they will ever so far commit themselves; these fortunate ones need read no further.

A new and rapidly-expanding industry is peculiarly liable to financial mishaps, since it invariably attracts a number of sanguine individuals who embark on the venture most inadequately equipped both as regards capital and experience, with the inevitable result that many too confiding friends suffer in consequence. We wish to refer more particularly to cases where, as in the one already alluded to, the business of an insolvent concern is being carried on under the old title, but with the addition of somebody's name, who writes "Receiver" after it, and obtains goods upon credit. We were glad to notice that under the decision of the Court of Appeal in this case the creditors succeeded in getting behind this title, and obtained judgment against the parties on whose behalf the Receiver ordering the goods was held in fact to have been trading, and who proved to be bankers holding debentures. As, however, one of the Lords Justices dissented from the judgment of his two colleagues, and the case is undoubtedly

Digitized by Google

one of importance to the trading community, it seems probable that the defendants' declared intention to appeal to the House of Lords will be carried out, so that the law on the subject unfortunately cannot be said to be finally settled. But in the meantime it may be permissible to say a few words about the position of traders supplying goods upon the orders of Receivers. We believe there is a widespread impression that the use of this title implies that the person using it has money behind him which entitles him to better credit than was, perhaps, ever enjoyed by the firm whose business he is carrying on. This is probably a survival of the notion that a Receiver may be presumed to be an official appointed by the Court. In former days this was usually a tolerably safe assumption, and in those cases where it still proves to be correct there may be some grounds for confidence. The Court always requires some evidence as to the credit of its officer before appointing him, and he has to find security for his duly accounting for the funds passing through his hands. He is, moreover, personally liable to those with whom he makes contracts; and, being usually a chartered accountant having a professional reputation to maintain, this is some check against any tendency to trade recklessly. At all events, it is generally not difficult to discover something about his credit and antecedents. It should, nevertheless, be borne in mind that a Receiver appointed by the Court is not allowed to carry on a business, as distinguished from realising it, unless he is specially authorised so to do by order of the Court, when he should use the title of "Receiver and Manager."

Things have, however, progressed a good deal further in recent times, and at the present day it would be most rash to assume that a person calling himself Receiver has any authority from the Court, or that he is a man of any substance whatever. By the Conveyancing and Law of Property Act, 1881, certain powers of appointing a Receiver were given to mortgagees which they did not possess before, and it has also of late years become a common practice to prepare debentures and debenture trust deeds in such a form as to enable debenture-holders or their trustees to appoint anyone they please as Receiver, with full powers of managing the business of the company which has made default. This Receiver may be a man of straw, who, while taking all the benefits of the business on behalf of the debenture-holders, is declared according to the terms of the deed, so far as his liabilities are concerned, to be the agent of the company granting the debentures, which presumably is insolvent when he commences his operations and probably immediately afterwards goes into liquidation. In the present case the Receiver who ordered the goods for which the action was brought is described in the report of the original hearing of the case before the Lord Chief Justice, as being himself a bankrupt. The Lord Chief Justice and two Lords Justices on appeal agreed in the opinion that this bankrupt Receiver was not personally liable for contracts he had entered into, but that some one must be, and accordingly they saddled this liability upon the persons from whom he derived his authority, and for whose sole benefit he was trading. On the other hand, Lord Justice Rigby, in a long and elaborate judgment, explained his reasons why he could not fix legal responsibility upon the bankers, and he avoided the dilemma as to no one being liable on the contract, by expressing the opinion that previously to the liquidation the Receiver was agent for the Company in accordance with the express terms of the debenture deed, and could pledge only its credit, and that afterwards he had in fact no principals, and so could pledge nobody but himself, and incurred personal liability for his contracts accordingly. Which of these doctrines will prove correct is, no doubt, a nice point for legal contention, and we shall have to wait for the answer until the final decision of the House of Lords.

Meantime it is a disagreeable revelation for debenture holders to find that they may, under certain circumstances, be rendered liable for the acts of their Receiver, but should the result of the appeal confirm this view it may lead to some amendment in the pernicious practice which has obtained hitherto, whereby a company having practically no subscribed capital is able to carry on business solely by means of money borrowed from the holders of debentures, to whom the whole of its assets are pledged. Such a company is entitled to no credit whatever, whether its affairs are managed by Directors or a Receiver, and it should get none.

Pending the ultimate issue of this conflict, and perhaps afterwards too, it behoves traders to remember that the safest rule is *caveat emptor*. Our advice for the present to those who desire to enter into contracts with a person using the specious title of Receiver is to inquire whether he is appointed by the Court, and whether he is a person to whom they would be willing to give credit when dealing on his own account. If not satisfied on both these points they will be wise to ascertain who his employers are, whether their credit is good and whether he has authority to pledge it. Failing a sufficient answer to these questions, or an adequate guarantee for the account, there is nothing left but to follow the famous advice given by Mr. Punch to those about to commit matrimony.

## THE ELECTROLYTIC DISSOLUTION OF CARBON.

Under this title has lately been published by Dr. Friedrich Vogel in the *Zeitschrift für Elektrochemie* an article which, on account of its dealing in a spirit fully critical with the work of Dr. A. Coehn, already recorded in *The Electrician*, will probably be of some interest to our readers. In order that the point of Dr. Vogel's criticisms may be the better apprehended, it may be stated that according to Dr. Coehn's results, it appears possible to cause carbon to act as the anode in a cell having sulphuric acid as an electrolyte and lead peroxide as a depolarising cathode, and, further, to obtain by the use of an external current a deposit of matter which, if not pure carbon, is at least richly carbonaceous. Three deductions from these results are made by Dr. Coehn, to wit: (1) It is possible to prepare a solution of carbon by electrolytic means; (2) carbon can be precipitated at the cathode from such a solution; (3) a cell can be prepared, of which the soluble electrode is carbon.

Dr. Vogel considers that the nomenclature used by Dr. Coehn is not sufficiently precise. Carbon has long been known to be capable of forming part of an ion acting in accordance with Faraday's law, but has not hitherto constituted such an ion. In the present case there is no evidence that this important gap has been bridged. Similarly, the carbon deposited at the cathode is associated with the elements of water, and cannot be considered as affording evidence of the previous existence of a carbon ion. Analytical data are also extensively lacking in Dr. Coehn's Paper. The figures on which the deduction of the composition of the deposit on the cathode is based should be given, and similarly an analysis should have been made of the products of the disintegration of the carbon anode (which is said to take place when the electrolyte is used at the ordinary temperature) and of the red-brown solution containing carbon (stated to be formed when the electrolyte is used hot). In Dr. Vogel's opinion the production of electrical energy by the electrolytic dissolution of carbon is not novel, for it has been described by Bartoli and Papasogli ("Nuov. Cimento," Vols. 8 to 13); the fact that Dr. Coehn has obtained better results than have these observers is to be attributed to his use of a cathode of lead peroxide.

The following amended version of Dr. Coehn's conclusions is therefore proposed:—(1) It has not yet proved possible (and the possibility is remote) to bring carbon into electrolytic

Digitized by Google

solution; (2) carbon has not hitherto been precipitated on the cathode as a chemical individual, but only as an integral part of a more complex ion; (3) cells having carbon as their soluble electrode have been devised by Bartoli and Papasogli and improved by Dr. Coehn.

The situation seem to present polemical possibilities.

## SOME ELECTRIC SUPPLY DATA.

Facts are stubborn things, and when once their certainty is fully proved there is no disputing the conclusions to which they directly lead. Gradually, year by year, the electric supply industry is piling up an immense quantity of facts, from which, it is to be hoped, we shall ultimately arrive at the truth as to the relative merits and demerits of the various systems of supply, and as to their suitability for particular kinds of localities and classes of work. And not only are the systems, as a whole, passing through the refining furnace, but each item in their management and working is being subjected to ultimate analysis; so that in the end we may expect

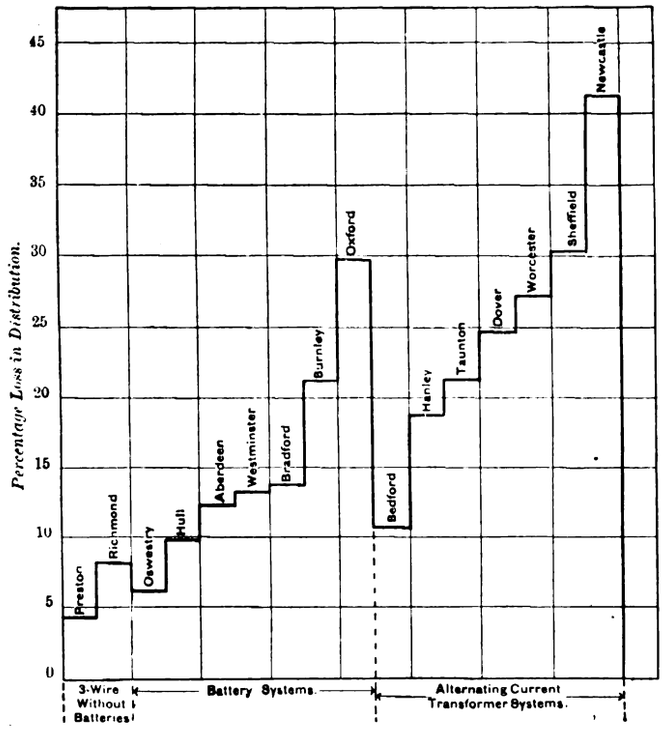

FIG. 1.—Percentage Loss of Energy in Distribution in some Electric Supply Systems.

to separate the elements of good from the elements of evil, and to be able to say with a high degree of assurance what particular combination of elements will form the best system for any given set of conditions. This, in fact, is the ideal towards which each year's additional experience carries the electric supply industry. The data now published at frequent intervals greatly assist in this process of "separating the sheep from the goats," and the accompanying Table I., showing what is done with the units generated, at a number of electric supply stations, should prove of further use in this respect, especially in regard to the relative efficiencies of the systems of distribution. It will, of course, be understood that a system is not necessarily condemned because it happens to show a lower efficiency of distribution. That would be but one factor to take into consideration. For instance, one alternate current system may have a lower distribution efficiency than another, not because it is intrinsically inferior, but because the load factor has been lower, causing the all-day idle and magnetising current losses in the mains to assume a greater relative importance. Or, again, in a battery system a higher efficiency may imply, not simply that better batteries and mains are in use, but that a better load factor and a more nearly constant load have reduced the call made upon the batteries and diminished the losses which have taken place in them.

As will be inferred from the foregoing remarks, one of the most important and instructive factors which can be brought into juxtaposition with the distribution efficiency of a system of supply, is the annual load factor of the station. Another useful factor is the ratio of the maximum actual demand on

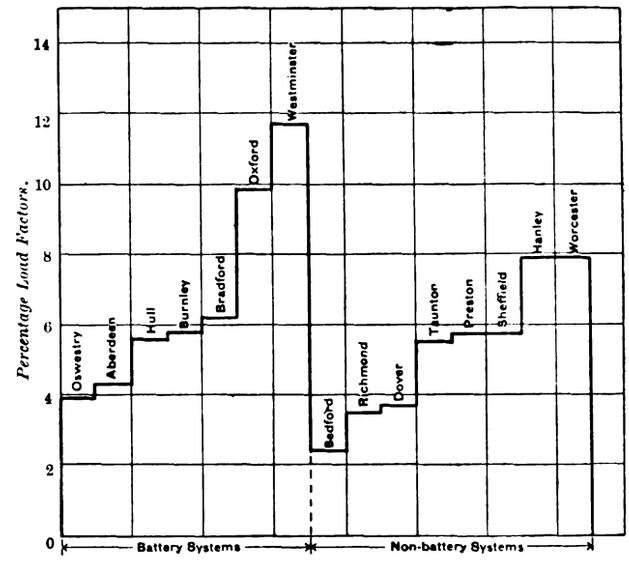

FIG. 2.—Percentage Load Factors of some Electric Supply Systems.

the station to the total capacity of the station. We have named this the "maximum demand factor." In a battery station this factor may, of course, exceed 100 per cent., though as a matter of fact it rarely does so; in a non-battery station it cannot, of course, exceed 100 per cent., unless the rated capacity of a plant is below its real capacity, and it is usually very much below 100 per cent. The maximum demand factor partly assists in showing to what extent there is superfluous

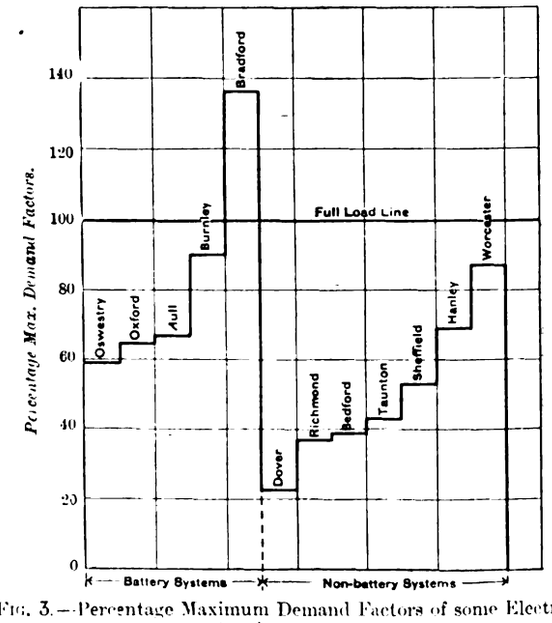

FIG. 3.—Percentage Maximum Demand Factors of some Electric Supply Systems.

generating plant; while the load factor indicates the extent to which the hours have been filled up by work. Table II. gives the load factors and maximum demand factors for a number of stations, arranged as far as possible to correspond with Table I.

A matter which is indicated in Table I. is deserving of further notice. We refer to the number of units used on the works. In the annual accounts of one or two of the electric

supply concerns these appear to have been confused with the units *wasted* on the works (mains, transformers, batteries, &c.). This is a highly original interpretation of the word "use"; and we have transferred units so "used" to a parallel column, which gives the units wasted or unaccounted for. In two or three cases where it has been impossible to separate the two items, these have been taken conjointly as units wasted. A literal interpretation of the returns of one concern could mean nothing else than that absolutely no units had been wasted anywhere; *all* were accounted for as "used." In the data for Oxford no account is taken of units used on the works, and the 87,552 units given are stated in the accounts to have been lost in the mains or unaccounted for. It is surprising to what a large extent some supply concerns consume, not their own smoke, but their own units. So important an item, indeed, is the amount used on the works that we have deducted it in every case from the total units generated before calculating the efficiency of, and percentage loss in distribution.

Finally, to afford some comparison between the load factors, maximum demand factors and the total and works costs of the concerns, we have compiled Table III., in which the stations in Tables I. and II. are arranged in the order of their respective load factors. We have also arranged the more important data diagrammatically, Fig. 1 showing to scale the percentage distribution losses, Fig. 2 the load factors, and Fig. 3 the maximum demand factors for a number of supply stations.

## HORSELESS CARRIAGES.

(FROM A CORRESPONDENT.)

The promoters of the Carriage Exhibition at the Crystal Palace have shown some ingenuity in advertising the show, as witness the fact that a number of people—a limited number, it is true—were induced to visit it one day this week, notwithstanding the unattractive character of the exhibits to all but the lucky few who possess carriages of their own. I count myself among the unlucky ones, and perhaps my views may be warped and jaundiced for that same reason. But I know a good deal about advertising, if little about carriages, and I cannot congratulate the management on their methods of pleasing their visitors after getting them on the spot. To begin with, "horseless carriages" has something alarming about it, like riderless horses; and this illusion is actually encouraged by the exhibitors themselves, who have profusely dotted the Palace grounds with warnings calculated to impress all pedestrians with the dangers of horseless carriage traffic. Passing along the winding roads which lead to the broad terraces, we thought at first that a novel kind of decoration had been introduced to ornament the borders, for at every 20 yards or so gaily painted poles with what appeared to be a little flag at the top of each, displayed themselves in long processional order like miniature venetian masts at a festival. What could this mean? Remembering, however, the object of our visit, I quickly divined that these gaudy indicators were to mark the track of the vehicles, to show them where they might go, and where not. Alas! for my discrimination; when near enough to examine one of these flags, which proved to be notice boards, imagine my horror to find myself face to face with the legend

"BEWARE THE HORSELESS CARRIAGE."

The next was the same, the next, and the next. Evidently there was no safety anywhere, whether I turned to the right or to the left, whether I hurried forward or retreated backward, the warning finger post admonished me to Beware! Stricken motionless with fright, and expecting to see the remorseless horseless carriage dart somewhere out of the shrubberies on either side of me, I was on the point of crying aloud for help, when happily I heard a noise in the distance, as if somebody or something were coming to my rescue. Turning a corner a little way ahead it proved to be something on wheels, which at first sight I mistook for an escaped perambulator, but which proved to be nothing less than the horseless carriage itself, careering along in fine style, and almost as intelligently as if a horse had been pulling it...

I say *almost*, and I use the word "careering" advisedly. A man was in it manipulating levers and wheels, and by his side were two or three passengers supposed to be enjoying carriage exercise. As to the exercise, there could be no doubt; but I am not so sure about the enjoyment. The creature swayed about and rocked in a rather alarming way—for the passengers; and the thumping of its machinery, to say nothing of the smell, could hardly conduce to the making of a "pleasant drive." My first impulse was to direct the passengers' attention to the warning on the boards, thinking it must have escaped them; but by this time the horseless carriage was nearly upon me, and I got out of the way for fear of upsetting it. I own to being afraid of carriageless horses, and always step aside for the stately steam roller; but this horseless carriage! Why am I to beware of the likes of it—and why, especially, if I am asked to buy one?

Making my way to the grand parade I read, and again read, the minatory notices as I go along, but now without any emotion save wonderment at the ineptitude of the people who placed them there. One of the horseless vehicles had just come to a standstill while fresh passengers, at a shilling per head, were being embarked. But I am wrong; it is not at a stand*still*; on the contrary it stands very noisy, and shakes itself to pieces almost with the effort of keeping going without going forward. Evidently this is a creature panting to be free—free to rush along and make the slavish pedestrian beware! I am given to understand that its spirits are kept up in this way because if allowed to run down, it requires a man to turn a wheel or something to make it start—like a certain perpetual-motion machine of Artemus Ward renown. On the whole, I fancy that if this affair were weighted with a good load of commercial travellers' samples, and the driver himself not too particular as to his seat, it might be found useful in a land where no horse is procurable.

Inside the Palace the carriages for horses had much the best of the show; and all the modern carriageless horses were greatly discounted by the presence of an ancient sample of locomotive, with cog wheels, compacted with a travelling carriage and guard's van all in one. Fancy travelling with the engine, furnace and boiler in the next compartment! Fancy also the egregious folly of people who want to recommend carriages of that *type* exhibiting such a monster by way of example!

There was an interesting display of ancient bicycles, but the most entertaining thing of all was a tricycle carrying appliances which are said to propel it at a great speed—a benzoline gas engine ignited by electric spark, we understood, was the motive power. But there was the usual saddle, as well as a pair of pedals! Nobody could tell us why. I suggested that a bath chair would be more comfortable, but the attendant seemed to think I was joking. He told me the owner's name, which at once accounted for the defective sense of humour betrayed in the concocting of this truly droll machine, and I came away with a suspicion that he must have had a good deal to do with the general arrangements, including the notices to "*Beware* of Horseless Carriages."

## ELECTRIC TRAMWAYS AND TELEPHONIC DISTURBANCES.*

BY JUL. H. WEST.

The disturbances which electric tramways generate in telephone circuits, especially those with earth returns, can be traced back to several causes. There is first of all the fluctuations of current which are unavoidable in the generation of continuous current by generators. Further, and perhaps the principal, cause of disturbance is the periodic variation of the resistance in consequence of the short-circuits at the commutator. Of the further causes Dr. Wietlisbach, in his article,† lays great stress upon the variations of resistance between trolley and wire, and states from experience that this variation is more marked in trolley lines than in tramways with slide contacts. The differences, however, which were shown in this respect by the trolley lines, made me suppose that the variations of the resistance between car wheels and rails, owing to the vibrations of the latter, were of far greater importance than the resistance variations between trolley and wire. In the *Elektrotechnische Zeitschrift*‡ of April 23rd the same opinion was expressed, and mention was made of some experiments which had been carried out in Berlin. The following is a description of these experiments:—

If the principal cause of disturbance be the vibration of the car wheels and rails, the noise created should vary considerably, according to the construction of the line. The noise should be greater on lines with hard foundations, such as concrete, than on lines constructed on elastic foundations, such as wood. The variations in the resistance in the former case must be far more marked than, and of a different frequency to, those that occur in the latter case.

To test this a line of the Berlin Tramway Company offered a splendid opportunity, as it possesses three different structural arrangements. Two small one-horse tramcars were connected by ordinary ropes—that is to say, by a non-conducting material. The two trucks were connected to a battery of two dry cells and the primaries of three induction coils, these latter being in parallel. The circuit was completed by the rails. The secondaries of the three coils were connected in series, and were in circuit with a Siemens telephone. The reason for using three induction coils with primaries in parallel was to make the resistance of the primary circuit as small as possible with the view of having any variation of the resistance between car wheels and rails brought out as distinctly as possible. It has now to be ascertained whether in running over sections of different construction the variations of the resistance between car wheels and rails exhibit a marked difference in character and intensity.

* From the *Elektrotechnische Zeitschrift*.
† See *The Electrician*, March 27, 1896, p. 725.
‡ See also *The Electrician*, May 1st, p. 22.

Digitized by Google

The experiments were carried out at night time from April 17th to 18th. The preceding day had been dry, and therefore the rail surface was dry, but as there had been a period of wet weather the bottom surface of the rails must have been moist.

The line selected consisted of the following sections :—

No. 1. 880 yards of line on longitudinal wooden sleepers.
„ 2. 88 „ „ stone paving.
„ 3. 900 „ „ asphalt.
„ 4. 330 „ „ stone paving.
„ 5. 220 „ „ asphalt.

In No. 1 section the line consists of girder rails mounted on longitudinal sleepers of pine wood of a section of 10 × 16cm. (4in. × 6½in.) The line here has a gradient of 1 in 28. Sections No. 2 to No. 5 have Haarmann ordinary tramway rails. Sections No. 2 and No. 4 are laid on a gravel basis as used in ordinary road construction. Sections No. 3 and No. 5 are laid on asphalt and concrete, the rails resting on a layer of concrete 12cm. to 16cm. (5in. to 6½in.) thick, on the top of which there is a 15cm. (6in.) layer of concrete and a 5cm. (2in.) layer of asphalt.

It was expected that the noise in the telephone would be weakest in the section with wooden sleepers, stronger in the sections with gravel foundation, and strongest in the sections laid on concrete. This assumption was later on confirmed.

The car travelled first over section No. 1 up the gradient, and a fairly strong noise could be heard in the telephone, like a quick repetition of the cracking noise a diaphragm makes when an interrupted current passes it. Now and then the noise ceased, which was probably owing to a fault in the conductor connecting the two cars. After this being adjusted the same section was again run over, but at higher speed. The noise was now continuous and of the same intensity as before. On entering section No. 2 a slight increase in the noise was noticed. A further, but much more marked increase in the noise occurred when section No. 3 (concrete foundation) was reached. Not only did the intensity increase considerably, but also the frequency of the sounds was distinctly greater than before. A decrease in the noise was noticed when entering section No. 4 (gravel), and again an increase in the noise when section No. 5 (concrete) was reached.

The end of section No. 3 forms a curve. But whether a further increase in the noise occurs here could not be ascertained with certainty. However, it must be remarked that the noise on this section was already so great that still louder emissions from the telephone were impossible.

On the return journey the second line was used. On passing the sections No. 5 and No. 3 at a speed of about 12 to 14 kilometers (7½ to 8¼ miles) an hour, a slight metallic tone could be noticed. At some points, curiously, the noise disappeared partly or altogether, especially so at the curve mentioned above. Most likely water covered the rails at these points.

The experiments show plainly *that the periodic variations of the resistance between car wheels and rails depend to a large extent upon the construction of the road bed.* It is desirable to further investigate this point and to arrive at a line construction which shall obviate the variation of resistance, and thus get rid of one of the causes of telephonic disturbances.

## ON RAILWAY TELEGRAPHS, WITH SPECIAL REFERENCE TO RECENT IMPROVEMENTS.*

BY W. LANGDON.

The subject with which this Paper deals is one which has not, for some time, claimed the consideration of members of this Institution. The progress which has attended the application of electricity to railway telegraph work is in no way comparable with that which has in recent years marked its progress in relation to lighting and power. Such advances as have been achieved are to be found more in minor details than in any radical change. Probably the most noticeable fact presides in the greater freedom from serious breakdowns which we now enjoy, and in the growth of the telegraph service—a striking testimony of its increasing utility. Competition is a stern and exacting master. The train service of to-day must not only be well equipped, but it must work well to time. That which yesterday was thought ample, is to-day found wanting. Each day ushers in fresh demands, greater elaboration, greater exactitude! How useful a factor the telegraph becomes in enabling this to be accomplished is probably known only to those in whose hands rests the responsibility of that which has to be done.

In the year 1880† the late Mr. Edward Graves, one of our Past-Presidents, and for many years our honorary treasurer, brought under the notice of members some extremely interesting statistics in relation to the progress of telegraphy, in which he produced a comparison between the mileage of wire and the number of instruments in use on the various railways in Great Britain in 1869 and 1879.

By the courtesy of the controlling officers of practically the entire railway service of the country—to whom my acknowledgments are gratefully tendered—I am, with the exception of the data of some two or three of the minor companies, enabled to bring forward this information another decade and a half. Accepting Mr. Graves's figures as a basis, and making allowance for the expansion of those systems, the returns for which are not to hand, we get the following approximate results :—

| —— | Year. | Miles. | Increase. |
|---|---|---|---|
| Mileage of wire employed for railway purposes ..... | 1869 | 27,204 | ... |
| | 1879 | 62,099 | 34,895 |
| | 1889 | 84,423 | 22,324 |
| | 1894 | 99,296 | 14,873 |
| | | Instruments. | Increase. |
| Number of instruments employed for railway purposes... | 1869 | 10,121 | ... |
| | 1879 | 46,847 | 36,726 |
| | 1889 | 100,590 | 53,743 |
| | 1894 | 130,339 | 29,749 |

It will be understood that these figures are not put forward as absolutely correct; they may, however, be accepted as fairly representative, and as a very near index of the progress and increasing influence of the telegraph service.

Prior to 1870 block signalling was but sparsely employed. During the decade 1869-79 it met with general adoption, which accounts for the large increase in both instruments and wire during that period. The increase during the half-decade 1894 is, in relation to that of the preceding decade, remarkable, as indicating that the expansion is still in active operation. These figures tell their own tale of utility in the management and regulation of railway traffic; while, from the mileage of wire maintained by the railways for the Postmaster-General, amounting approximately to some 67,000 miles, it may be reasonably inferred that the railways are in no small degree contributing to the convenience of that branch of the public who, from day to day, seek the service of the Post Office wires. Let us pause but a moment to consider how the present enormous traffic of our railways, or the mass of matter which daily passes over the various telegraph services of the country, could possibly be dealt with without these aids, or how the conditions of commercial life would be affected by their cessation, and we at once become sensible of their value.

Individually, possibly few railways afford a more forcible illustration of the rapid growth of a railway telegraph service than that to which the author is attached. In 1878 the total mileage of wire on the line amounted to 9,816 miles, and the number of instruments to 7,702. The mileage of wire to-day exceeds 22,000, and the number of instruments closely approximates to 19,000.

This large expansion is naturally calling for increasing accommodation for wires, and, in the interest of economy, for a careful study of the cost in both construction and maintenance.

### Poles.

One of the chief factors to which we are indebted for the greater stability of our lines of telegraph at the present time is the employment of poles which have been charged to a certain extent with creosote.

In the session of 1873-74 a Paper,* "On the Preservation of Telegraph Poles," was read before this Institution, then the Society of Telegraph Engineers, in which the various processes for the preservation of timber were discussed. Of the several methods there referred to, the creosoting process may be regarded as the sole survivor.

Creosoted poles are now almost universally employed. Their life, or the period they may remain in position without deterioration from decay, is still, to all intents and purposes, undetermined. Given a properly seasoned pole, fairly dry when placed under the process, its life may reasonably be relied upon to cover the period the pole is required to stand before additions or alterations call for its replacement. It is neither necessary nor desirable that the timber of telegraph poles should be completely charged with creosote. The quantity of creosote impressed into telegraph poles is usually 8lb. to the cube foot of timber; and this quantity, where the wood is properly seasoned and well dried, will be found to have penetrated to the core or heart-wood of the pole. It will thus form a complete protective shell, impervious to moisture; and in this lies the main advantage of the application. Timber which is thoroughly impregnated or saturated with creosote becomes, as soon as the oil is dissipated, devoid of much of its elasticity, and is then more easily broken than if the heart-wood of the timber is allowed to remain uncreosoted.

There are points where creosoted poles are objectionable—such, for instance, as station platforms. Here, whereas in former years

Digitized by Google

Memel timber was usually employed, it is preferable to use pitch pine. Pitch pine is more durable than Memel. It is more resinous, and thus more antagonistic to the reception of moisture; and it is the moisture which, traversing the fibre of that portion of the timber in the soil, under the influence of the warmer atmosphere above the ground line, disintegrates it at, or about, the ground level, and so destroys it.

The number of wires which have now to be accommodated, in many instances, call, not merely for stout poles, but for structures, such as "H" poles. These structures (Fig. 1) consist of two poles, A, B, braced together at the foot by a slab of wood, C, as nearly as possible at right angles to the poles, and a further slab, D, some 4ft. from the butt end of the poles, arranged diagonally; the arms, E, at the top of the poles act as the tie-pieces at that end of the structure. These are sometimes, especially in high poles, supplemented by a stiff iron rod, F, passing through the two

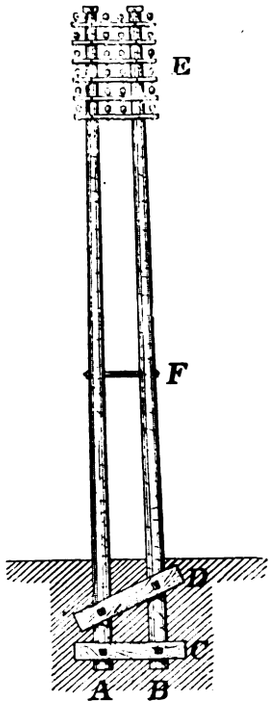

Fig. 1.—"H" Pole.

poles, at right angles to them, or by rods, crossing one another diagonally, tied together in the centre.

The practice has been to allow the two poles forming the basis of this structure to have a slight spread at their butt ends; *i.e.*, taking a centre line down the poles, the distance between these lines at the top of the poles being some 12in. less than that between the centre lines at their butt ends. When poles become crowded with wires, this, with respect to the lower arms, detracts from the regularity of the insulators and wires. It is better that the poles should be equidistant throughout. You have then merely to provide for the increasing thickness of the timber in order to ensure perfect regularity in the position of the wires from top to bottom.

The Midland Railway having recently been called upon to construct for the Postmaster-General a section of an important trunk line to Scotland, it has been necessary to convert an existing line of single poles into an H line. To construct these H poles, braced together at the foot, as shown in Fig. 1, would have meant the replacement of the entire line—a most expensive operation. Under these circumstances the existing line of poles has been allowed to stand. At the proper distance a pole, B (Fig. 2), to match the standing pole A has been placed in position, care being taken to cut off the butt end so as to ensure a flat basis. It has then been allowed to stand some days, so as to become well settled in its position, after which slots for the arms are cut to correspond with those on the original pole. The short arms are then, one by one, removed from the latter, and replaced by arms 56in. long, which are bolted to the two poles. Where the old line of poles has been systematically constructed, with the arms, say 12in. apart, centre to centre, the appearance of such a combination is in every way agreeable to the eye.

It will be evident that without the diagonal tie-piece the pole might, under stress of wind, work themselves out of position. This has to be met by staying them in the same manner as a single line. Where, from exceptional causes, the poles cannot be stayed, the diagonal tie-piece should be employed. Photographs of sections of the line of poles thus treated are on the table.

H poles are destined to be of great service. There is no reason why the number of wires should be limited to four on an arm. The 56in. arm may be replaced by a 72-in. arm, accommodating six wires, thereby increasing the capacity of the poles one-third. We may even venture beyond this where the need for it exists, employing either iron arms, or wooden arms of larger scantling, in order to meet the weight of the wires standing on the outer side of the poles. The structure is one which, if well stayed, will withstand gales far better than single poles with half the number of wires, arranged for two on an arm. Moreover, it will be observed that H poles, with six wires on an arm, lend themselves to telephone requirements. With the wires arranged two outside each pole, and two between the poles, three groups, or squares, may be formed by each pair of arms—each wire of each "square," or "group," being maintained 1ft. apart. A photograph of poles so armed is on the table.

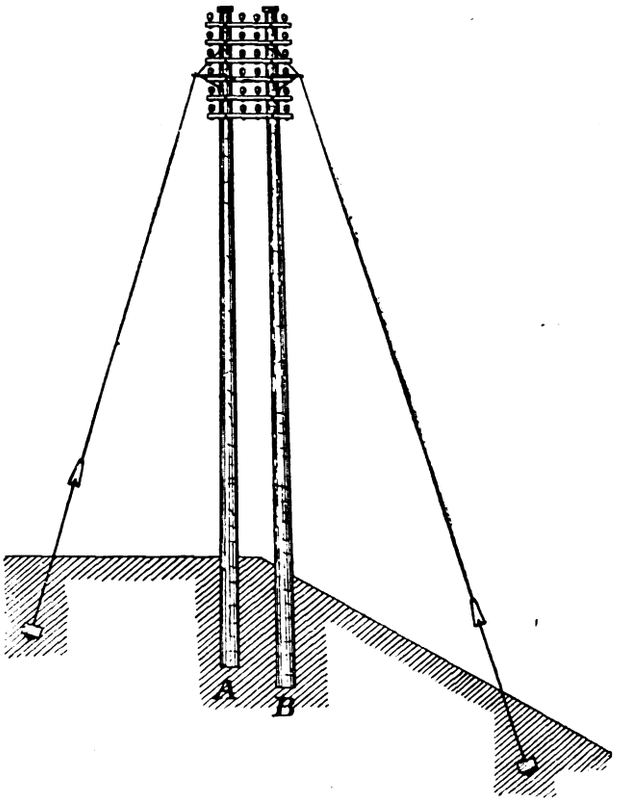

Fig. 2.

Telegraph poles seldom commend themselves to the observer as an æsthetical subject; but uniformity in construction, with the poles well in line, or regularly following the contour of the road, evenly graduated for height, and uniformly armed and wired, with, perhaps, an ornamental top in exceptional places, will do much towards removing those objections which are not unfrequently raised against their presence.

### Arms.

In the trimming of poles the most novel feature is the introduction of iron arms; 40in. tubular iron arms, specimens of which are before the meeting, have been employed for some 100 miles of the trunk telephone line recently erected by the Midland for the Post-

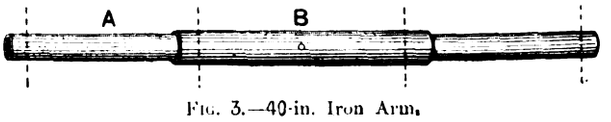

Fig. 3.—40-in. Iron Arm.

master-General. Some years prior to this, shorter arms—tubular and rectangular, for carrying two wires—were experimentally employed by the author. No inconvenience whatever has, so far, attended their employment.

The longer (40in.) arm (Fig. 3) is composed of 1¾in. galvanised iron tubing, A, ⅛in. thick, strengthened by a piece of larger gauge tubing, B, of same thickness, 2in. in diameter, carried over the centre portion of the 1¾in. tubing. The two tubes thus combined are practically homogeneous and very strong.

The employment of these arms admits of a slight reduction in the length of the insulator bolt, which may with advantage have the shoulder of the bolt, as also the washer, hollowed out to fit the

Digitized by Google

arm. Thus arranged, there is no possibility of the insulator twisting round. These arms should be very durable, and it is worthy of remark that they do not require so much of the pole cut away as is necessary for the wooden arm.

The earth-wiring of wooden arms has, the author believes, in some quarters, been abandoned. That course has not been pursued on the Midland. Earth-wiring, as illustrated by the sample placed upon the table, is still followed. With iron arms the need for earth-wiring disappears. It is merely necessary to lay the main earth wire securely under the washer of the arm bolt.

Clearly, where iron arms are employed, failure in insulation such as that produced by a broken or cracked insulator will readily make itself known. To what extent this will operate with respect to the iron arms experience must show. In a trunk telephone line discrepancies in the insulation of the four wires forming a square would appear to be undesirable factors. Whether such failure may be more readily traced with iron than with wooden arms has yet to be proved. The iron arms ought, where "earth" is the cause of failure, to give a more defined fault, and thus lead to its more ready removal. Iron arms and brackets, as well as iron poles, have, in various forms, been in use for years, especially for foreign lines; and probably no member of the Institution has a more intimate knowledge of their value than our Past-President, Mr. Alexander Siemens.

In slotting round poles for these iron arms it was at first thought that a V-shaped cut would readily lend itself to the reception of the arm; but experience has shown that it is better to slightly slot the pole, as though for a rectangular arm, and gouge out the base of the slot. The pole being round, the V-shaped cut fails to retain the arm in that rectangular position in relation to the pole, which is necessary to give the line that trim and uniform appearance so acceptable to a good workman.

In the employment of wooden arms there is nothing of a novel character to record. They are to-day very much as they have been during the last 20 years. It may not, however, be inopportune to raise the question whether English oak is the only timber from which they should be made. Doubtless English oak is more durable and stronger than other timber; but it is a question whether foreign oak—say Stettin—if cut under the conditions applicable to English oak, viz., well seasoned, free from knots, and free from sap, is not sufficiently durable and strong for the purpose. Arms cut from this description of timber have been in use on the Midland system for many years, and nothing has transpired to create a want of confidence in its suitability for such work.

Another point worth considering is that of painting the arms. Paint, if applied when the timber is properly seasoned and dry, is, no doubt, beneficial; but paint applied to wood which does not possess these qualifications produces dry rot, and is, consequently, absolutely injurious to the timber, and dangerous to workmen when on the poles. Where the arms can be stacked by the user until thoroughly seasoned, they may with advantage be painted.

### Staying.

It is no exaggeration to say that to the more perfect manner of staying the telegraph lines of the present day, and to the employment of machine-stranded staying wire, are we indebted for that greater immunity from heavy breakdowns which we enjoy at the present time. It is, in cases of snow falling under those conditions which cause it to cling to the wires, a question of strength of pole *versus* strength of wire. Needless to say it is preferable the wires, rather than the poles, should suffer; and, as a rule, such is the *status* at which well-built telegraph lines of the present day have arrived.

On railways there is usually more room for staying poles than is the case on roads. The greater the spread of the stay the greater its advantage. In order to be of the greatest service its attachment to the pole should be somewhat above the centre of the full complement of wires which the pole is designed to carry. It is seldom, however, one can determine the number of wires which a line shall ultimately support, and thus it is well to fix that point which may be most serviceable under any condition. The practice pursued by the author has been to fix the upper stay behind the third and fourth arm, and where a second stay is required—as is frequently the case with heavily wired lines—between the eighth and ninth.

Formerly the practice was to form the stay on the pole, wire by wire. A single wire was first attached to the pole and strained up tightly to the stay-rod; then a second wire was attached and strained up, as nearly as could be judged, to the same degree of tension; and so on, till the necessary strength was attained. The objection to such stays is the absolute improbability of so arranging the several wires of which the stay is composed, that each shall bear its share of the strain. As a rule the strain falls upon one wire more than another. Under great stress this wire is the first to give way. The rest follow in like manner.

With machine-stranded staying wire, each wire bears its own proportion. If properly stranded—*i.e.*, with a long lay—it is easily handled. Where attached to the stay-rod it should be passed around a pear-shaped eyelet. To Mr. W. H. Preece, C.B., F.R.S. Past-President, we are indebted for the introduction of machine stranded wire for this purpose. Staying wire should be of a steely character. The Midland specification provides that each No. 8 gauge wire (which is the only gauge used for stranded staying wire) shall stand a strain of 1,800lb., with a maximum stretch of 4 per cent., without breaking, and that it shall bear 12 twists in a length of 6in. without fracture and without scaling.

An excellent device for binding stranded stay-wire has recently been introduced by Mr. Roberts, of the Postal Telegraph Department, which enables the workman to accomplish his task well and with ease. The tool itself will be found upon the table.

The strand wire is first bent so as to form the loop around the stay thimble, A (Fig. 4), the splicing tool B being employed to draw it closely into the groove. The free end of the stay-wire is then unstranded and the wires straightened out as shown at C. One wire, D, is picked out for the purpose of forming the first lap of the binding; the tool is then employed to arrange the remaining wires symmetrically parallel with and around the main strand, so that they may bind into it without spoiling its circular shape. The free wire is now placed under the hook of the stay tool, which is revolved around the stay and the remainder of the wires. When the first selected wire has been used up another is chosen, and the same course followed with each until all have been evenly bound around the main stay.

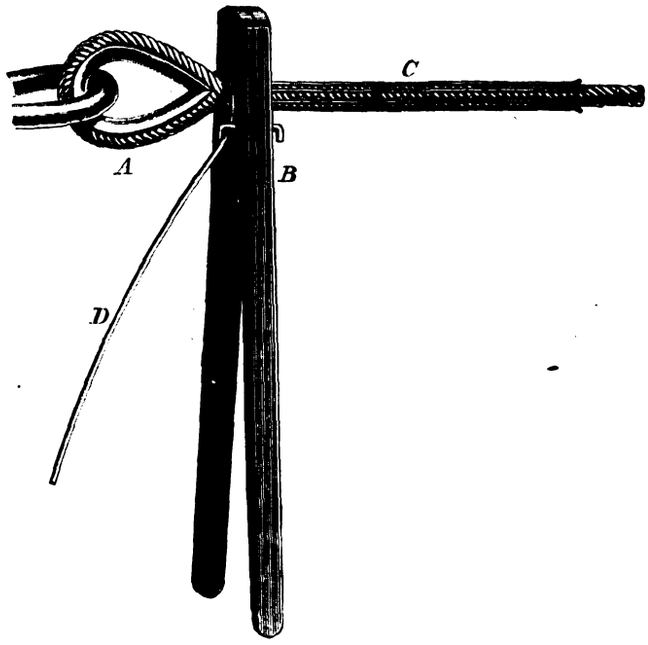

Fig. 4.

All stay-rods planted in soil formed of cinders or ashes should be protected by fillets of creosoted wood, or they will rapidly succumb to the electrolytical action set up by the ashes and the galvanised iron. On railways it frequently happens that the top ballast is composed entirely of refuse cinders or ashes.

### Insulation.

For many years a practice has prevailed of using a minor form of insulator for short circuits or block signalling wires. The author raises the question whether such a degree of refinement is desirable. It is inconvenient, inasmuch as it does not admit of interchange of wires where such changes are desirable. On the Midland the practice has long been abandoned. But one class of insulator and one gauge of iron wire—viz, No. 8, is employed. Thus, when required, through wires may be joined in with the shorter lengths, and the uniformity of the line preserved by maintaining the shorter lengths below the longer ones. Moreover, it would appear that, however important other wires may be, none can be more important than those which govern the movements of the trains.

It is believed that the best insulators are those known as the "Post Office" and the "corrugated," samples of which are on the table. Samples of the form of terminal insulator and leading-in cup, employed largely by others, as well as by the author, are also before the meeting. The terminal insulator is made in two sizes, the smaller kind being employed where the strain is small, as, for instance, for leading across from one side of the line to the other for signal box and other like purposes. The larger kind is employed for terminations of line wires.

The great advantage of this insulator resides, not merely in the shape of the ware, but in the extent of the bolt, A (Fig. 5), which,

Digitized by Google

it will be seen, passes far beyond the corrugations at which point the line wires are attached—a provision which renders it practically impossible for a wire to fall, even when the porcelain is from any cause broken. Another advantage is that these corrugations, or grooves, not only help the insulation, but make provision for the attachment of different gauges or different descriptions of wire, as, for instance, if it is desired to attach a No. 11 to a No. 8. If the No. 8 is placed in the lower groove, and the No. 11 in the upper groove, the strain on the bolt will be about equalised, and the insulator will retain its vertical position. They are equally useful for joining two descriptions of wire, say iron and copper, the one being terminated on one ring, and the other on another, the two wires being joined by a loop.

At the termination of all important wires, and, in many instances, at important signal boxes, "leading-in" cups are employed. They are formed (Fig. 6) of a porcelain tube, A, in which the G.P. wire is threaded, the tube being contracted at B so as to keep the wire central and free from the edges of the tube. This tube is protected by an iron hood, C, perforated so as to admit of the rain cleansing the porcelain tube.

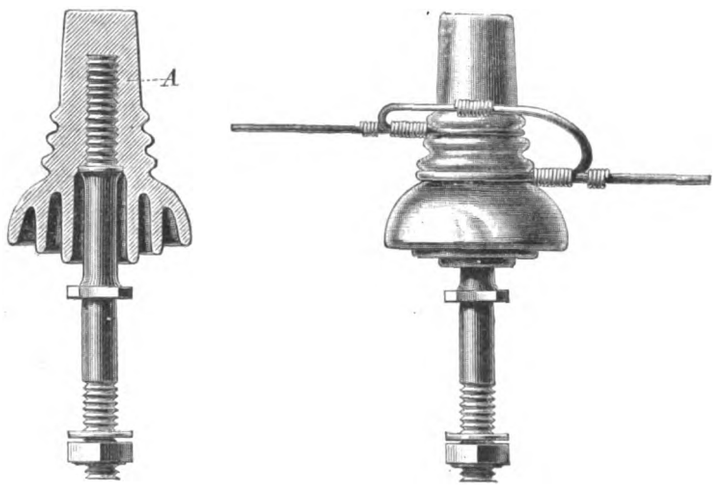

Fig. 5.

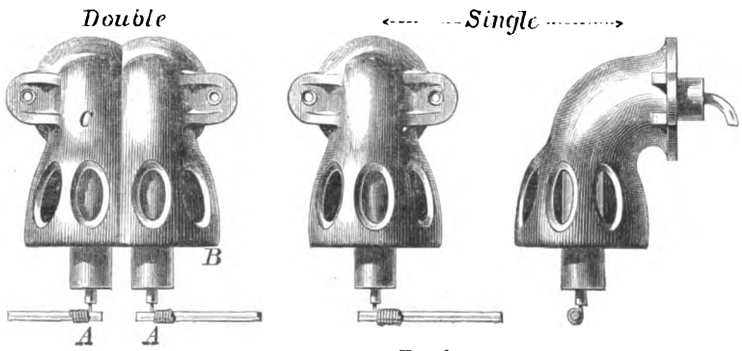

Fig. 6.

Where round creosoted poles are employed for leading-in wires, it is necessary to carry the G.P. wires in boxing fixed between the arms. If this boxing is strongly made it will admit of the leading-in cups being fixed to either side of it, and will thus form a very complete and durable termination.

### Wire.

Considerable progress has of late years been made in the employment of copper wire. The first copper wire erected for telegraph purposes was, it is believed, that erected by Mr. A. Graves, of the North-Eastern Railway, at York, about 1877. Mr. Graves on that occasion employed No. 14 gauge (0·080 S.W.G.); and shortly afterwards, in 1880, copper wire of the same gauge was erected on the Midland. The copper wire of various gauges in use on the Midland now extends to some 5,000 miles, of which 3,000 odd is maintained for the Post Office.

The objection to iron wire is the shortness of its life and—in comparison with copper—its higher electrical resistance and greater inductive capacity. Under the auspices of the Post Office a class of iron wire largely superior to that formerly in use has for some years past been obtainable. This improvement—embracing conductivity and the general construction and character of the wire—does not, however, extend to prolongation of life. In a few years, more or less, dependent very much upon the condition of the atmosphere, the galvanising is gone, rust sets in, and thereafter the strength of the wire, as also its conductivity capacity, rapidly degenerates. Covered iron wire is frequently found to be of great service in smoky localities. The best is that served with what is known as West's compound. The wire is lapped with cotton, and then passed through a special liquid composition, so that the cotton covering may become saturated by it. It differs from all other covering processes in that the composition hardens when exposed to the air, is unaffected by changes of temperature, and when hardened is impervious to wet. So long as the covering remains sound the wire beneath it retains its original condition, and when the covering is removed appears as fresh as when new. A sample of some of this wire which has been in use on the Midland for some years will be found on the table.

The conductivity resistance of a 12½ gauge (0·097) copper wire is 5·034 ω per mile; that of No. 8 (0·160) gauge galvanised iron wire is 12 ω per mile. The breaking strain of the 12½ copper is 490lb.; that of No. 8 galvanised iron, 1,100lb. The cost of a mile of 12½ copper is about £4. 4s.; the cost of a mile of No. 8 galvanised iron wire, £2. 10s. The difference in price is considerable, but against this we are able to place many advantages, durability—which means less cost in renewal, a saving of certainly two out of three, which at 20s. a mile more than covers the additional cost; reduced strain, and less load on poles, which admits of their reception of a greater number of wires: and last, though not the least important, less liability to fracture.

It is probable that 12½ copper, or possibly a slightly larger gauge, will entirely supersede galvanised iron wire; for, although when new the galvanised iron wire has the advantage in tensile power, it retains that power a portion of its life only, and during the latter part of its existence its tensile strength is even less than that of the 12½ copper. Its electrical resistance is, even when new, more than twice that of the copper wire.

It is desirable in using 12½ gauge copper wire, where possible, to slightly reduce the length of span—to limit it to 70 yards on the curve and 75 on the straight—say 24 poles to the mile instead of 22. In all newly constructed lines for the Midland Company's own purposes, copper wire is now used; and in the renewal of existing wires, iron is, as a rule, being replaced by copper.

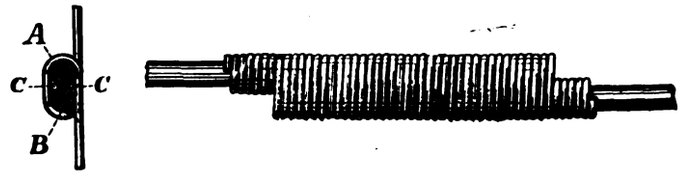

Fig. 7.—Joint as used by P.O.

In the erection of either copper or iron wire, the degree of tension to which the wire is pulled up is a factor which plays an important part in its durability. Wiremen, until they are taught otherwise, have a profound contempt for the effect of temperature upon the material they are using. On a hot summer day, or a bleak winter morning, they will pull the wire up to the same degree of tension. The consequence is that the wire erected under its maximum expansion in the hot noontide, is either broken or stretched under the influence of a lower temperature. The dip, or the stress, imparted to a wire must always be governed by the temperature, for which purpose a thermometer, placed in a position analogous to the wire must be used.

Where wires are run on the parallel system, if the top wire is erected to the required degree of tension, the eye of the wireman can, by it, readily regulate other wires in the same span. To impart to this wire the proper degree of tension, its stress must be determined by its "dip," or by what is known as an indicating tension-ratchel—the latter by preference.

Where wires are erected on the "revolving" system, it is impossible to avoid the use of the tension-ratchel if the wires are to enjoy a uniform degree of tension.

To Mr. W. H. Preece, C.B., F.R.S., we are indebted for much careful investigation of this important question, and by his courtesy I am enabled to add, in the appendix to this Paper, tabulated statements adopted by the Post Office showing the stress at which both copper and iron wires should be erected at various temperatures.

### Jointing.

The "Britannia" joint still holds its own, whether for iron or copper wire, but the ends, or "tails," which for years have been left bent up, are now cut clean off, it being evidently better for a joint to *draw* than to form an intermittent fault. The Post Office, with regard to copper wire of large gauge, before soldering fill the insterstices between the two wires, A, B (Fig. 7), and the binding, by two pieces of smaller gauge wire, C. The object is to facilitate the soldering of the joint, and so prevent overheating the copper.

Digitized by Google

The joint when completed is wiped clean and allowed to cool. It should not be overheated, and it should not be chilled.

Where joints are made in this manner a jointing frame becomes necessary. This consists merely of a couple of clips, C, C (Fig. 8), in which the ends of the wire are held. It can with convenience be fixed by the legs L L to the wiring barrow, or the legs may be thrust into the ground : and here, perhaps, although a minor matter, it may not be out of place to call attention to an improved "wiring barrow" which has recently been brought into use. These

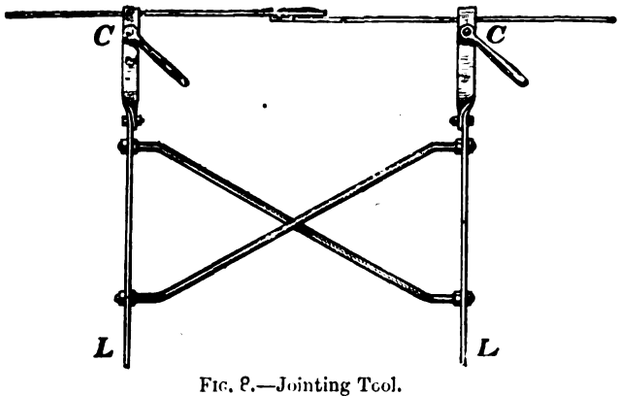

Fig. 8.—Jointing Tool.

barrows are made with a frame similar to that of a garden barrow, but longer. The drum for the reception of the wire is made of sheet iron, and works vertically, instead of horizontally as hitherto. Ordinarily the barrow is wheeled along the sides of the line by one man, as on a public road ; but where it cannot be wheeled, two portable arms, provided for the purpose, are placed in position, and the barrow is then carried in the usual manner by two men. The arrangement will be understood by reference to the photographs on the table.

### Binding.

For many years the author has abandoned the use of No. 16 galvanised iron wire for binding, and has employed in its place a specially made No. 11 G.I. wire. It is necessary this class of binding wire should be more ductile than the ordinary conductivity No. 11 G.I. wire, and that it should be capable of being lapped around a No. 8 wire without scaling. If it scales it will rust, and the oxide will be carried by the rain down the outside of the insulator cup, to which it will adhere to such an extent as may, in damp weather, materially affect the insulation of the wire.

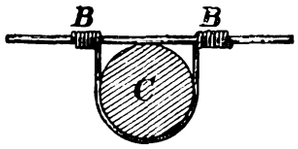

Fig. 9.

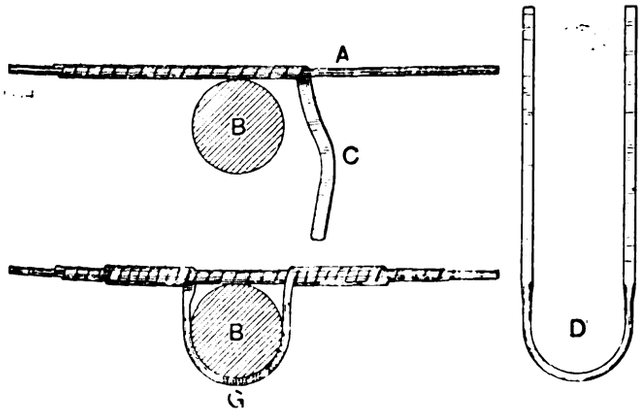

Fig. 10.

In Fig. 9, C represents a cross section of an insulator, at the point at which the binding wire is attached. The binder is merely lapped some five times around the line wire, as shown at B. It will be found that this form of binder will prevent a broken wire from running back quite as well as any form of binding with No. 16 gauge wire. Its advantages are : great durability, absence from stretch under influence of gales, less cost in construction and maintenance, and greater freedom from chafing—the line wire being much more firmly held.

The practice thus pursued by the author has, in a modified form, been adopted by the Post Office with respect to copper wire. That portion of the line wire, A (Fig. 10), which rests against the insulator, B, as well as the portion which is to be lapped by the binder, is first overlaid by a copper tape, C—a piece of copper wire rolled out flat. The binder, D, is formed of a large gauge wire which has its two ends flattened so as to be readily laid around the taped portion of the line wire. Both the tape and the binder are first laid on by hand, the copper strip being exceedingly ductile, and finally tightened by the aid of a suitable pair of pliers, the complete binding being as shown by G (Fig. 10). Samples of these binders and tapes, as well as of the complete form of binding, are on the table.

The author is of opinion that wherever a sufficiently ductile wire can be obtained for the purpose, it is better to employ a binder of a gauge equal, or nearly so, to that of the line wire.

The Post Office, under the direction of the engineer-in-chief, have recently issued tables of sizes, weights of tapes and binders for the different gauges of copper wire, which, by Mr. Preece's permission, I have the privilege to append to this Paper.

*(To be concluded)*

## LONDON COUNTY COUNCIL.

*New Electric Supply Stations.*

At the weekly meeting of the London County Council it was agreed, on the recommendation of the Building Act Committee, that approval be given to the plans submitted on behalf of the Chelsea Electricity Supply Company for the construction of a generating station at the corner of Alpha-place of greater extent than 250,000 cubic feet, subject to the usual conditions ; that the plans submitted by the Charing Cross and Strand Electricity Supply Corporation for the construction of a generating station at Commercial-road, Lambeth, be deviated from in some particulars ; and that sanction should be given to the plans submitted by the Vestry of Hampstead for the construction of a boiler house and engine room addition to the electricity station at Lithos-road.

*Tramway Syndicate.—Electric Traction.*

The Highways Committee reported on the suggestion made by the County of London Tramway Syndicate that arrangements should be entered into between the Council and the Syndicate for the immediate transfer to the Council of all the tramways in the county of London, such tramways to be afterwards leased to the Syndicate for a term of 28 years. The combined rents, the Syndicate estimated, would be about £200,000 a year. The Syndicate proposed that an underground system of electrical traction should be adopted on all the lines, the cost of the necessary works of reconstruction being borne by the Syndicate, and all such works immediately on completion becoming the property of the Council. The entire cost of equipment and plant for electrical power, it was suggested, should be borne by the Syndicate, but should at the expiry of the lease be purchased by the Council at a valuation to be determined by arbitration. The Committee considered it inadvisable that the Council should allow such a Syndicate to act as intermediaries, and as to the 28 years' lease, as the whole of the tramways would come under the Purchase Clause of the Tramways Act by 1910, it would be undesirable to extend the lease beyond that period. As regarded the statement that the Syndicate would be prepared to pay a rent equal to the net earnings of the line during the years preceding the grant of the lease, they were in some doubt as to how it could be done. The proposed reconstruction of the lines to adapt them for electrical traction would of necessity take considerable time, and would interfere with traffic and cause a diminution in the receipts. The Committee further pointed out that it had not yet been demonstrated that the principle of electric traction on the underground conduit system was capable of being worked successfully, and it would be a serious matter for the Council, if after the alteration of the lines had been carried out, the system were found to be a failure. There was another point in connection with the system proposed, namely, that it would involve the placing in the streets of rails with a slot varying from ⅛in. to ¼in. wide, which might cause accidents to the ordinary vehicles using the roads. It appeared so doubtful whether the system would prove successful that they ventured to think that the anticipation that by its adoption the leasing syndicate would be in a position to pay a rent equal to the present net earnings of the lines was somewhat sanguine. They therefore recommended that no arrangements should be entered into with the Syndicate with reference to the tramways in the county of London.

Mr. WESTACOTT (Chairman of the Committee) asked permission to postpone the matter for a fortnight, and this was agreed to.

The same Committee reported having received a letter from the North Metropolitan Tramways Company stating that under an arrangement between the Directors of that Company and those of the London Street Tramways Company the Council were asked if they were prepared to consider a proposal for the immediate sale to the Council of the two companies within the county, and for a subsequent lease to the first-named Company, the Companies to sell the lines for £437,000 to which had to be added the £101,788 already paid by the Council for parts of the line now leased to the Company. In the opinion of the Committee the purchase of the line at £10,000 a mile would be a favourable transaction to the Council, and put an end to all disputes and litigation. The Company were willing to lease the lines for 14 years, and pay a fixed rent of

Digitized by Google

£45,000. The Companies' representatives stated that if the Council should consider that some form of electric traction should be adopted the Company will be prepared either to carry out the necessary works on terms to be arranged, or, should the Council itself execute the works, to pay either a fixed rent or a share of the extra profits which might be derived from the use of such traction. The Committee recommended that the Council should enter into a provisional agreement for the purchase of the property of the two Companies, and for the subsequent lease to the North Metropolitan Tramways Company on the terms set forth in an accompanying agreement. The clause in the agreement relating to electrical traction was as follows:—"Not to use, except with the consent of the Council in writing, other than animal power upon any of the lines included in the lease; provided that if the Council shall hereafter consider that the adoption of electric or other mechanical power is advisable, the Company or the Council, at the option of the latter, shall carry out the necessary works on terms of payment by the Company of a fixed rent on the expenditure, and either with or without a share of extra profit derived from the use of electric or other traction, or otherwise as may be agreed."

Mr. WESTACOTT asked that this report might also be postponed for a fortnight. Agreed to.

*Estimated Expenditure on Electrical Works.*

Amongst the other estimates of expenditure for 1896-97 the Highways Committee reported that they would require £1,538 for expenses in acting otherwise than as local authorities under the Electric Lighting Acts and Orders, towards which it was estimated that they would receive £500 for electric meter testing fees. The estimated expense showed an increase of £275, and fees £300. For the purposes of the London Overhead Wires Act of 1891 it was estimated that £550 would be required, and for the cost of inspection and maintenance of subways £765, of which amount £700 was estimated to be recoverable from companies using such subways.

Mr. WALTER EMDEN asked when the motion with regard to subways referred to the Highways Committee (and reported at the time in *The Electrician*) would be considered, for at present they had heard nothing of it.

Mr. WESTACOTT replied that a joint committee which had been formed would, he believed, discuss the matter at their next meeting.—The statements were agreed to.

*Lighting of the Thames Embankment.*

On the question of voting £10,555 for the maintenance of the Victoria, Albert and Chelsea Embankments.

Mr. DICKINSON asked what had been done with the £1,000 voted for the purposes of electric lighting.

Mr. WESTACOTT said the Council applied for an Act of Parliament to put an electric lighting station on the Thames Embankment for the lighting of the embankment and bridges. The question as to whether that should be done or not had been before the Council on many occasions. Some time ago the Committee agreed to do it, but the Council referred the matter back. The whole matter would be considered by the Committee at their next meeting, and then it was for the Council to say when the Committee reported if they should go into the expenditure or not.

Lieut.-Col. FORD said that under an Act of Parliament which they got seven years ago the Council were empowered to light Westminster and Waterloo Bridges by electricity, and he would like to know if that matter was being considered.

Mr. WESTACOTT replied that the matter would be considered by the Committee at its next or following meeting.

*Fire Alarms and Telephones.*

The Fire Brigade Committee estimated that £8,750 would be required in the coming year for the telephone (about 120) and electric fire alarms (about 580). This showed an increase of £750. It was further estimated that £500 would be required for electric bell work at the stations.

## CORRESPONDENCE.

### CURRENT MEASUREMENT BY MEANS OF STANDARD RESISTANCES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice in your issue of the 1st inst., an article by Mr. W. C. Fisher on the measurement of current by means of a standard resistance and a determination of potential difference. It is interesting to note that such resistances were used by Dr. Hopkinson in 1879 for this purpose (*see* his book on "Dynamo Machinery," p. 15), and to my knowledge Messrs. Siemens Bros. were using them in the form of plates for central station work in 1889; but the method is much older than either of these dates, and is, I believe, due to Poggendorff. During the last five years I have impressed upon the students in this laboratory what was already well known, viz., the importance of current-flow in such resistances, illustrating my remarks by the curves as shown in Fig. 36 of Mr. Fisher's article, which were obtained in this laboratory in 1891 on a plate measuring 26in. by 8in. and 3·5mm. thick.—Yours &c., E. WILSON.

Siemens' Laboratory, King's College, W.C.
May, 4, 1896

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. Wilson's letter, proof of which you have kindly sent me, I have only to say that whether the method of measuring current by means of the fall of potential over a standard resistance is due to Poggendorff, or is anterior to that gentleman, I do not know; he is usually credited with it, and as I do not recollect ever having seen any contradiction I presume the statement is correct. By stating that Messrs. Crompton were the first makers of large standards—that is to say, having a current capacity of 1,500–2,000 amperes—I did not for one instant intend to advance *their* claim as *originators*; on the contrary, the context proves otherwise, and the statement, such as it is, is, of course, open to correction. With reference to the last paragraph, I can only say that the potential curves shown in Fig. 36 formed the concluding portion of the investigations, and were completed, I believe, before or about the commencement of the period of time mentioned, and up to the present the writer was utterly unaware that *similar* curves were in the possession of Mr. Wilson, or that he had investigated, or even advocated, the use of such standards.—Yours, &c., WM. FISHER.

Crompton Laboratory, Thriplands, Kensington-court,
London, W., May 6, 1896.

## LEGAL INTELLIGENCE.

### Electric Construction Corporation v. South Staffordshire Tramways Company.

The further hearing of this case (fully reported in last issue) was duly resumed on Friday last before Mr. Justice Romer.

At the close of the evidence for the defence,

Mr. EVE decided not to call rebutting evidence, as Sir F. Lockwood said he limited that part of the case affecting the evidence of Mr. Thomas Parker to the evidence of Mr. Courtenay.

Sir F. LOCKWOOD said that whatever view might be taken on the main features of the case, it was one that required thorough investigation. The two men Ebbsmith and Wain had admittedly conspired together to defraud the South Staffordshire Company, and that being so the whole thing must be looked at with suspicion. It seemed to him a most extraordinary thing that any company could have been found to accept a contract such as the one in question.

His LORDSHIP said he should like to ask what Mr. Wain's object could have been in entering into a contract which he must have known would mean bankruptcy to the Company.

Sir F. LOCKWOOD pointed out that at this time (1891 and 1892) Wain was absolutely at the mercy of Ebbsmith.

His LORDSHIP said he should doubt whether Wain was so absolutely at the mercy of Mr. Ebbsmith as to do an injury to a Company out of which he was to get no benefit for himself.

Sir F. LOCKWOOD said that in this particular case they had conduct that was absolutely inexplicable otherwise than by accepting the explanation he had. In conclusion, he submitted that they had here a contract impossible of performance. The evidence as to that was in the hands of those who had accepted it. They accepted it with their eyes open, and they agreed to obligations that were most extraordinary. The question which should be asked in this case was, would it have been possible for such a contract to have been entered into by the South Staffordshire Company unless that Company had been betrayed? The answer to that was, No. He contended that it was a fraudulent contract brought about by fraudulent means, and whether the Directors of the plaintiff Company knew it or not they were not on their guard, and did not make inquiries, and therefore they could not take the benefit of the frauds of their agent.

In replying on the whole case Mr. EVE said that the real point and practically the only one, was that the contract was brought about by a chain of fraud, and was so tainted with fraud that it could not stand.

Mr. OSWALD, Q.C., said there remained the question of penalty and its being *ultra vires* under the Act of Parliament, and mentioned certain cases on which the defendants relied on those points.

Mr. EVE said that on the question of *ultra vires* he should rely on the case of the Attorney General *v.* the Great Eastern. On the question whether the contract was tainted with fraud, he submitted that the evidence did not support any such contention, for up to the end of 1893 there was no suspicion that the men with whom the Company were dealing were not only perfectly honest, but these men were at the very head of their profession, and it was not until just before the trial of these men this year that the details of the frauds were discovered. It was said that the terms of the purchase were onerous.

His LORDSHIP said that it was first said it was not their interest to have electricity at all.

Mr. EVE replied that his Lordship would be guided in that by the evidence.

His LORDSHIP said that the first point was that, being in want of money, the plaintiff Company must be taken to have known that the defendant Company could not have performed the contract.

Digitized by Google

Mr. EVE pointed out that the defendant Company had obtained power to provide electricity, and having the power they set to work to find a Company to supply the motive power, and when the plaintiff Company entered into the contract they knew the Company could not purchase for cash, and it was under these circumstances that the contract was made both a working and financial one. He submitted that, taking everything into consideration, it was not a case in which the plaintiff Company should be so far put upon inquiry that they would impute fraud. If that was disposed of, then the question whether it was an onerous contract was not before the Court. He submitted that the charge of fraud had not been proved. The onus of proof rested with the defendants in this case, and though they had properly raised every conceivable suggestion against those who had acted dishonourably to them, they had not brought home to the Corporation any knowledge of or responsibility for those acts. He asked, therefore, for a declaration that the contract was binding on the defendant Company, that an account be directed on that footing, and that the counterclaim be dismissed with costs.

His LORDSHIP intimated that he should reserve judgment.

### Goodman v. Smith.

The importance of a clear understanding at the start was shown in an action at the Westminster County Court on Wednesday, in which the plaintiff, a dealer in electrical appliances, sought to recover payment of an account of £14. 10s. in respect of electrical fittings supplied to the order of defendant. The plaintiff was called and said the defendant ordered the goods in question quite in the ordinary way, and never said a word about their being for a third party until payment of the account was pressed for. There was no foundation for the suggestion that he stated that he was acting as the agent of a Mr. Hooper, and had he done so the goods would not have been supplied on credit. For the defence Mr. William Smith was called and said he had previously done business with the plaintiff on his own account, and had always paid him for the goods supplied; but in this particular instance he distinctly told the plaintiff that he was giving the order on behalf of a man of the name of Hooper, who was well known to him. In giving judgment his Honour said it was a question of oath against oath, and he was not prepared to say that either party was saying anything which they knew to be false. At the same time he was not satisfied that the defendant made it clear that he was giving the order in the capacity of agent for a third party, and therefore judgment would be for the plaintiff for the amount claimed, with costs.

## TRADE NOTES AND NOTICES.

*[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]*

**SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d. abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations**

### NEW BOOKS AND EDITIONS.

*The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. The NEW EDITION is NOW READY. Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition now ready. Price 2s., post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from Notes made by Mr. Parshall in his capacity as chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables. 30s., post free.

"COMPREHENSIVE INTERNATIONAL WIRE TABLES FOR ELECTRIC CONDUCTORS."—By W. S. Boult, price 5s., post free.

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d. Will be ready first week in June.

TENDERS INVITED.—The vestry of Hammersmith require tenders for (*a*) supplying and laying high-pressure and low-pressure cables and pipes, (*b*) supplying and erecting arc lamps and lamp posts, (*c*) supplying and erecting transformers and sub-station equipment, (*d*) supplying and erecting a 5-ton overhead travelling crane. Specifications, &c., can be obtained of Mr. A. H. Preece, 39, Victoria-street, London, S.W., and tenders must be delivered at the vestry offices, 57, Fulham Palace-road, Hammersmith, by noon of Wednesday, May 27th. Mr. W. P. Cockburn is vestry clerk. Some further information was given in our advertisement columns last week, and will appear in next issue.

——— The Bray Town Council invite tenders for the supply and delivery of a 75-kilowatt steam alternator, a 200 H.P. Lancashire boiler, a 100 H.P. vertical high-speed engine, a fuel economiser, feed pump, &c. Tenders to Mr. P. MacDonnell, Town Hall, Bray, by the 18th inst.

——— The Municipal Authorities of Medina de Rioseco (Valladolid) invite tenders for the concession for the electric lighting of the town for 20 years. Tenders to El Ayuntamiento de Medina de Rioseco (Valladolid), Spain.

——— The General Direction of the Bulgarian Posts and Telegraphs require tenders for the supply of a quantity of porcelain insulators, bronze and iron wire and iron hooks, of a total value of about £6,130. Tenders to the Direction, at Sofia, by the 13th inst.

——— The Municipal Authorities of Penaranda de Bracamonte require tenders for the concession for the electric lighting of the town for 15 years. Tenders to El Secretario del Ayuntamiento, Penaranda de Bracamonte, Spain, by the 28th inst.

——— The General Direction of the Roumanian Posts and Telegraphs, Bucharest, invite tenders for the supply of 21¾ tons of copper and bronze wire. Tenders by the 15th inst.

——— The Municipal Authorities of Voghera invite tenders for the concession for the electric lighting of the town on the expiration of the present gas concession (1898). Particulars from L'Amministrazione Communale, Voghera, Italy.

——— The Secretary of State for India invites tenders for iron telegraph posts. Tenders to the Director-General of Stores (Mr. J. Parker), India Office, Whitehall, S.W., by 2 p.m., on the 19th inst.

——— Tenders are required for the lighting of the City of Bucharest for five years. Tenders must be sent in to the Town Council by June 24th.

——— The Great Eastern Railway Company require tenders for the supply of various stores, including telegraph materials, india-rubber, &c. Tenders to the Secretary, Liverpool-street Terminus, E.C., by 10 a.m. of the 14th inst.

——— The Oldham Town Council require tenders for the supply of a Lancashire boiler 28ft. long by 7½ft. diameter, to work at a pressure of 125lb. Tenders to Mr. A. Andrew, Gas and Water Offices, Oldham, by the 12th inst.

——— Tenders are invited for the installation of the electric light at "Woodlands," Gisburn (Lancs.), for Mr. C. J. Massey, J.P. Specifications from Mr. C. Parsons, architect, 9, Grimshaw-street, Burnley.

——— Tenders are required by the Portsea Guardians for the wiring of part of the workhouse for the electric light. Tenders to the Clerk (Mr. S. R. Ellis), Guardians' Offices, Portsmouth, by the 15th inst.

TENDERS ACCEPTED.—The Derby Town Council have ordered two further transformers from Messrs. Siemens Bros. and Co., at £268, and a 1½ H.P. motor for coal hauling at £32. The tender of the British Insulated Wire Company for the supply of cables, junction boxes and jointing at £2,185, has also been accepted.

Digitized by Google

TENDERS ACCEPTED.—The Hammersmith Vestry have accepted the tender of Messrs. S. Z. de Ferranti (Limited) for the supply of three rectifiers for £1,044. 15s.

——— The Shoreditch Vestry have accepted the following tenders for the supply of electrical plant and machinery for their electricity station: Section A, steam engines (Willans type) and dynamos, Electric Construction Company (£14,879); Section B, steam and exhaust pipes, boiler pumps and cast-iron work, Thames Ironworks Company (£4,500); Section C, motor transformers and sub-station apparatus, Electric Construction Company (£2,890); Section D, battery of accumulators, Pritchetts and Gold (£610).

——— The tender of Messrs. Benham and Sons (Limited) has been accepted by the Metropolitan Asylums Board for steam-piping work at the Brook Fever Hospital. The amount of the tender is £1,200.

——— Twenty-five tenders were received for the supply and erection of generating plant, &c., for the lighting at Ferniehurst, Baildon (Shipley Station) ranging from £630 to £1,461. The work has been let out in three sections to different contractors.

——— The Great Grimsby Town Council have ordered a dynamo from Messrs. P. R. Jackson and Co. for lighting the Town Hall for £145. 10s.

TENDERS RECEIVED.—For putting down electric light installations (including four steam engines, four dynamos, 174 arc lamps, &c.) at the Elberfeld and Barmen railway stations, tenders were submitted by German firms exclusively as under (in marks):—

| | |
|---|---|
| Union Elektricitäts Gesellschaft | 124,683 |
| Siemens and Halske | 121,223 |
| Körting Gebrüder | 116,000 |
| Edward Herhahn | 114,126 |
| Rd. Beckmann | 105,596 |
| Allgemeine Elektricitäts Gesellschaft | 104,015 |
| M. Schorch and Co. | 100,181 |
| Naglo Gebrüder | 97,988 |
| L. Brandes | 96,142 |
| Lahmeyer and Co. | 90,115 |
| Schuckert and Co. | 88,848 |
| Eggersmann and Lang | 88,841 |
| Helios Company | 86,920 |

The above was for Lot 1 (Elberfeld-Döppersberg station), and the list shows that the same differences between the highest and lowest tenders prevail in Germany as here. For Lot 2 (Barmen-Rittershausen station) the difference was not so marked—highest 89,922, against 61,202 marks=28,718.

——— The Hampstead Vestry have received tenders from the following firms for the supply and erection at the electricity supply station of steam alternator, switchboard, &c. The tenders are under consideration:—Babcock and Wilcox, Wm. Boby, Brush Company, Crompton and Co., Davey, Paxman and Co.; Easton, Anderson and Goolden, S. Z. de Ferranti, W. J. Fraser and Co., K. and H. Lupton, C. A. Parsons and Co., J. Penn and Sons, Siemens Bros. and Co., J. E. and S. Spencer, and Wright's Patent Heater Condenser Company.

WESTINGHOUSE ENGINES FOR SALE.—An important list of engines for sale by the Metropolitan Electric Supply Company will be found in our advertisement columns, including engines of 320 I.H.P., 250 I.H.P., and 85 I.H.P., all fitted with variable expansion gear controlled by flywheel governors.

APPOINTMENT VACANT.—The Governors of the People's Palace require a professor of physics. Salary £150 per annum, with a capitation fee. Applications to People's Palace, London, E., by 31st inst.

DISSOLUTIONS OF PARTNERSHIP.—Messrs. Frank Catt and Herbert Ellis Hall, electrical engineers, New Wharf, Tonbridge, Kent, have dissolved partnership.

——— The partnership business hitherto carried on under the style of Alfred Arculus and Co., electric light globe and shade makers, Birmingham, has been dissolved.

NEW FIRM.—Mr. J. Hermann Field has joined Mr. F. H. Taylor, late of 17, Ironmonger-lane, London, E.C., and the firm have taken offices at 14, Victoria-street, Westminster, S.W. Both gentlemen have been engaged for many years in electric light and power work, Mr. Taylor in London and Mr. Field in Ireland and Scotland.

BUSINESS CHANGES.—An amalgamation has been effected between the Nalder and Harrison Construction Syndicate (Limited) and Swinburne and Co. (Limited). For the purposes of this amalgamation it has been found advisable to dissolve the Syndicate, and the amalgamated businesses will in future be carried on as a private firm under the title of Messrs. Nalder and Hilton, who have purchased the two businesses. This arrangement is to date from March 1st, 1896, and a special resolution for the above-mentioned voluntary liquidation of the Syndicate has been passed. It is anticipated that the combination of interests and the concentration of the business will be of advantage to the firm and to their numerous clients.

LIQUIDATION.—It has been decided to wind up the Tramways Electrical Traction Company (Limited) voluntarily, and Mr. J. Barber Glenn, 7, Poultry, E.C., has been appointed liquidator.

FAILURES.—Charles Alfred Fletcher, described as an electrician, late "victualler," of Ashton-under-Lyne, has filed a deed of registration with his creditors.

THE HOTEL CECIL.—In connection with the opening of this hotel, we are informed that upwards of 6,000 electric lights have been fitted, together with telephones, and an electric system of ventilation, under the supervision of Mr. Morgan William, C.E., of 39, Victoria-street, S.W. Current is taken from the mains of the Charing Cross and Strand Company until a separate plant is erected under the supervision of Mr. R. Hammond. The electric fans, which are placed in the dining, smoking, coffee and billiard rooms, are of the Blackman Company's make. Those in the dining room are capable of dealing with nearly 1,000,000 cubic feet of air per hour, and those in the coffee and billiard rooms about half a million feet in each case. The lavatories are similarly ventilated.

DOULTON CONDUIT SYSTEM.—It has been decided to employ Doulton conduits for the entire system of mains at Shoreditch (London) and Leyton (Essex), the work of laying in both cases having been commenced by the contractors.

PRICE LISTS WANTED.—Messrs. Swete and Baker, electrical engineers, Johannesburg, notify in our advertisement columns that they wish to receive price lists of electrical plant, apparatus and fittings.

AN AMERICAN SUNBEAM.—The "Sunbeam" Incandescent Lamp Company of Chicago, who are the makers of a large variety of incandescent lamps for various purposes, are making a speciality of their 20-watt 4 c.p. lamp, which is made for voltages from 50 to 120. The advantage of this choice of voltage is that several lamps may be grouped in series on distributing mains of any pressure and controlled by one switch. This is a useful arrangement where the lights are required to be in groups, as in shops and other business interiors, and especially where they are employed for decorative purposes. Another out of many uses for this style of lamp is found in illuminated advertising signs.

THE "ENGINEERING MAGAZINE."—The contents of the May number of this excellent magazine are of the usual varied and interesting character, and include:—"The Present Value and Purchasing Power of Gold," by H. M. Chance; "Quackery in Engineering Education," by Edgar Kidwell; "The Vast Importance of the Coke Industry," by John Fulton; "Development of Electric Lighting Engines," by H. Lindley; "Are British Railroad Stocks Good Investments," by Thos. F. Woodlock; "Electricity and the Horseless Carriage Problem," by Wm. Baxter, jun.; "Points in the Selection of Steam Engines," by W. H. Wakeman; "Modern Machine Shop Economics," by Horace L. Arnold; "Minor Mineral Products of the United States," by David T. Day; "Restraints upon the Practice of Architecture," by John Beverley Robinson. The usual exhaustive review of the world's Press is also given. This number, as well as all the back numbers, may be obtained at the offices of the European Edition, 1; 2 and 3, Salisbury Court, Fleet-street, London.

EXPORTS OF ELECTRICAL APPARATUS AND MATERIAL.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from April 29th to May 5th, with the ports of destination:—

*Argentina*—Buenos Ayres, £547. *Australasia*—Adelaide, £1,210; Brisbane, £6; Melbourne, £236; Newcastle, £5,455 (Electric Mining Machinery); Sydney, £367. *Belgium*—Antwerp, £20; Brussels, £384. *Canary Islands*—Teneriffe, £9. *Ceylon*—Colombo, £66. *Denmark*—Copenhagen, £1,771. *France*—Paris, £643. *Holland*—Amsterdam, £30; Rotterdam, £28. *India*—Bombay, £47; Calcutta, £178. *Panama*, £261. *Portugal*—Lisbon, £32. *Russia*—Odessa, £333. *St. Helena*, £4. *South Africa*—Cape Town, £730; Durban, £134. *Straits Settlements*—Penang, £24; Singapore, £56. *Sweden*—Stockholm, £12. *Uruguay*—Monte Video, £46.

*Foreign-Made Electrical Apparatus and Material.*—Foreign made goods have been exported from this country, as follows:—

*Argentina*—Buenos Ayres, £55. *Australasia*—Brisbane, £80.

EXPORTS OF TELEGRAPHIC WIRE, &c.—The Board of Trade returns show that the exports of telegraphic wire and apparatus connected therewith, for the month of April, were £23,066, against £35,544 in April, 1895, and £186,739 in April, 1894. For the four months of 1896, the exports have been of the value of £211,368, against £99,746 in the corresponding period of 1895, and £452,018 for 1894.

TRAMWAY REQUISITES.—We have received a copy of a paper on "Self-acting Rain-proof Seats and Signal Bells for the Outside of Tramway Cars and Omnibuses" by Mr. C. Challenger, the traffic manager of the Bristol Tramways and Carriage Company. Everything bearing on tramway equipment has an interest at the present time, and Mr. Challenger's paper will therefore be appreciated.

Digitized by Google

NOTES ON ALUMINIUM.—The British Aluminium Company (Limited) have recently issued a handy pamphlet entitled "Notes on Aluminium and its Alloys." The contents comprise a brief history of the development of the aluminium industry, some useful notes on the properties of the metal, descriptions of the processes of melting, casting, forging, rolling and other treatment in working the metal into its finished shape, and a number of useful tables. As the treatment of this the newest of commercial metals is in many respects of a special character, metal workers and others might derive useful information by a perusal of this pamphlet.

WILLING'S PRESS GUIDE.—The extremely useful and compact "British and Irish Press Guide," issued by Messrs. Willing, of 162, Piccadilly, and 125, Strand, London, is just published, and will be found as replete as ever with condensed information of service to those who have occasion to consult such publications. Much more ambitious and less accurate "Press Guides" are issued than the shilling book of Messrs. Willing.

"ANUARIO DE LA MINERIA, METALURGIA Y ELECTRICIDAD DE ESPANA."—We have received a copy of the 1896 issue of this Anuario, now in its third year of publication. To those having business connections with Spain, and to exporters of mining and electrical machinery, the work cannot fail to be of assistance. Naturally the greater part of the book is devoted to mining matters. Government Departments (Agriculture, Interior and Marine), and their chief officials, mining undertakings and their engineers, commercial treaties, tariffs, railway charges, &c., are included in the book. The work has been carefully revised by Don Román Oriol, Professor of the Madrid School of Mines, and is issued by the *Revista Minera, Metalurgia y Electricidad*.

"CASSIER'S MAGAZINE."—The May number of this magazine contains articles on "Electric Power from the Montmorency Falls in Canada," by C. C. Chesney; "An Historical Electric Central Station," by John W. Lieb, jun.; "Cooling System for Condensing Water," "Power Distribution in the Cylinders of Compound and Triple-Expansion Engines," "Fire Boats," "American Naval Engineers, their Rank and Title," "Economies in the Foundry," and "The Washing of Gold Placers in South America."

---

ABERDEEN.—The report on the extension of the electricity works recently presented by the Electrical Committee has been considered by the Council, and it has been decided to make certain extensions at the station at an estimated cost of £4,500. It has further been decided to put in two new boilers, with feed-water heater and feed pumps, at an outlay of £3,000. Some small extensions of the electric light mains were also agreed upon at a cost of £580. The question of extending the mains to the West End and to the Harbour District was deferred.

BANGOR.—The Board of Trade having decided not to sanction the Council's application for an electric lighting licence, a Provisional Order is to be applied for.

BATH.—Prof. A. B. W. Kennedy, who was recently appointed to value the works and mains of the City of Bath Electric Lighting and Engineering Company, has now presented his report, which states that, with the exception of the arc lamps and pillars, the whole of the buildings, plant and mains are in excellent working order. The Company has spent £38,359 on land, buildings, plant and mains, and it had been suggested that the Corporation should offer £15,000 for these. The site is described as an excellent one, capable of easily carrying additional direct-driven plant which would double the present capacity of the station. As to the plant, although this is not of the newest type, it has been kept in admirable order and condition by Mr. Metzger, the Company's engineer. Summing up, Prof. Kennedy considers that the proper sum to be paid by the Corporation for the buildings, plant, mains, &c., is £24,533, leaving for separate consideration the question of the arc lighting plant with lamps and lamp-posts. The Corporation's advisers had strongly objected to the arc lighting as it stood, and he had no doubt a considerable amount of the feeling against it had been caused by the excessive distance between the lamps, and that if the same lamps were used at half the distance apart, as they ought to be, the lighting would be more satisfactory. On the other hand, there had been a number of serious failures of the arc lighting, and in practically every case it had been proved that this was due to causes connected with the defective construction of the lamp-posts or their connections. The actual design of the lamp-post had been chosen by the Corporation, but he considered them so defective that he was bound to decide that they were entirely obsolete and unsuitable, and therefore he could put no value upon them. The Electric Lighting Committee have decided to recommend the purchase of the Company's undertaking on the basis of the figures in the report. In case the Corporation should also decide to take over the arc lighting plant, Prof. Kennedy stated that his valuation will be increased by £1,954, in which figure no value is placed upon the lamp-posts. The report and Committee's recommendation were considered by the Urban Sanitary Authority at their meeting yesterday.

BELFAST.—In moving the adoption of the minutes of the Electric Light Committee at the last meeting of the City Council, Councillor Andrews said that his Committee had under consideration the question of the erection of a steam generating station so that they might be in a position to supply electric current to the whole of the city, and they hoped to lay a report before the Council on June 1st. They would, however, be compelled to ask the Corporation for land, or for money to purchase land, to serve as a site for the new station.

BOLTON.—The Joint Committee of the Streets and Electric Lighting Committees have decided to recommend the introduction of electric traction on the local tramways, that the overhead system be adopted, and that the lessees of the tramways be invited to confer with the Committee as to commencing the adoption of the system.

BRISTOL.—The report recently presented by the Electric Lighting Committee on the question of extensions was considered by the City Council on Friday last. An abstract of the Committee's recommendations was given in our issue of the 24th ult. The Chairman (Mr. Pearson) moved the adoption of the report, and referred to the difficulties they had at first encountered, but the conveniences of the present station far outweighed the initial difficulty they had in piling the site, and justified the heavy expenditure they were thenc alled upon to incur, and he was satisfied that no blunder had been made. He had no hesitation in asking the Council to go on with the works on that site, which would involve an ultimate but not an immediate expenditure of £75,000. The result would be that, whereas with the original station the cost per lamp was about £3, with the suggested increase the cost would only be about £1. 16s. When the proposed works were completed the available power would be equal to about 5,000 H.P. The number of lamps connected in March, 1894, was 9,750; in March 1895, 16,362; and in March, 1896, 29,210. During the last half year, after paying expenses and interest on the sinking fund, there was a profit of about £1,500, which they proposed to utilise for making good the deficiency that would arise during the current half-year, the period of their lightest load. They had every reason to anticipate that the revenue for the year ending September next would be not much under £12,200. Therefore, he felt justified in saying that they were not costing the city anything this year, and he believed that the future demand upon the rates (if any) would be very trifling. It was proposed to spend £5,000 during the year on buildings, and in 1897 £3,000 more, and £11,500 on additional machinery. In 1898 they contemplated spending a further sum of £8,000 to complete their buildings, and about £7,600 for further machinery; and in 1899 a further expenditure for equipment of about £5,700 would be necessary. A sum of £16,000 would be required to carry out the extensions of mains in streets which the Committee had in their minds at the moment, but it was not intended that the whole of this money should be spent straight off. £4,000 has been set aside for contingencies, and £8,000 for house connections, the entire aggregate being £74,000 odd. The report did not deal with the arc lights, as the Committee were not directly responsible for the city lighting; but Mr. Pearson said if the lamps were doubled or trebled it would be a very small matter for the Committee. He would, however, remind the public that they could not expect a street magnificently lighted with the electric light for the same price as they would get the darkness rendered visible, which was the usual accompaniment of gas, although candle for candle electricity was infinitely cheaper than gas. In the discussion which ensued various members put in pleas for the extension of the mains to particular thoroughfares, and one or two councillors dealt with the tramway question. In reply, Mr. Pearson said he had no ambition to see Bristol lighted with incandescent electric lamps, which he considered did not do justice to the electric light in the streets. As to the Tramway Company he had no desire to anticipate a report which they would be called upon to consider later on, but the Committee were able to supply a large amount of current for motive power if required. The report was adopted.

BURNHAM (ESSEX).—A scheme for the electric lighting of this village has been submitted to the Parish Council by Messrs. Donnison and Co. A meeting of ratepayers is to be held to discuss the matter.

BURY ST. EDMUNDS.—The National Telephone Company have decided to establish a telephone exchange in this town.

CANTERBURY.—The Town Council have decided to establish an electricity supply station and to apply to the Local Government Board for sanction to borrow £20,000 for that purpose. Electric light will be introduced into the cathedral as soon as current is available. Mr. R. Hammond has been appointed consulting engineer to the Committee.

CENTRAL LONDON ELECTRIC RAILWAY.—The contractors for the construction of this railway (the Electric Traction Company, Limited) have let the sub-contracts for the construction of the various tunnels, and it is stated that work will be commenced on

Digitized by Google

all the sections early in July next, and be completed about October, 1897.

CHELMSFORD.—At the last meeting of the Town Council the minutes of the Lighting Committee stated that they had considered the offer of the Chelmsford Electric Lighting Company to sell their undertaking, including the Provisional Order, works, machinery mains, &c., for £34,828, but were unable to make any recommendation on the matter without the advice of an expert, and asked for the assistance of a consulting engineer to advise them. The whole question is shortly to be considered by the Council in Committee. A contract has been entered into with the Company for lighting the town for five years upon the same terms as heretofore, viz., £20. 10s. per arc and £2. 6s. 10d. per incandescent lamp per annum.

COLCHESTER.—The Town Council have selected a site for their electricity works, and tenders have been invited for the supply of the necessary plant from the Brush Company, Messrs. Christy Bros., Crompton and Co., Messrs. Siemens Bros. and Co., John Fowler and Co., and C. A. Parsons and Co.

COUNTRY HOUSE LIGHTING.—Messrs. Drake and Gorham have recently secured contracts for the electric lighting of "Woolton" for Capt. Wingfield, Stratford, and also for fitting-up Mr. Frank Barlow's county house at Lynchmere.

CROYDON.—The County Council intend to apply to the Local Government Board for sanction to borrow a further sum of £5,000 for electric lighting purposes.

DERBY.—The Local Government Board have declined to sanction the Council's application to borrow, amongst other sums, £419 for costs incurred in obtaining their Provisional Order.

DOVER.—At the next meeting of the Town Council Mr. Fry will move that a sub-committee be appointed to visit Rouen for the purpose of inspecting and reporting upon the electric traction system employed on the tramways of that city. Several members of the Council are anxious that the town should possess efficient tramways, and are favourably disposed towards the overhead electric traction system.

EXETER.—The Board of Trade have revoked the Exeter Electric Light Company's Provisional Order.

EXHIBITIONS.—We have to chronicle the formal opening of no fewer than six exhibitions during the week, and of this number three are British—viz., the International Horseless Carriage Exhibition at the Crystal Palace, the Motor Car Club display at the Imperial Institute (London) and the Cardiff Exhibition, which promises to be a great success. The other exhibitions are being held at Berlin, Budapest and Geneva, and are of international and industrial importance.

FULHAM (LONDON).—The consideration of a report by Mr. F. H. Medhurst on the question of the adoption of a joint electric lighting and refuse destructor scheme has been adjourned until after the forthcoming Vestry elections.

GATESHEAD.—The Town Council recently received an application from a firm of electrical engineers for authority to lay electric light mains, and the matter was referred to the borough engineer (Mr. James Bower), who recommends the Council to themselves apply for a Provisional Order. If the Corporation decides to adopt the electric light, he suggests they should start on a small scale so that the initial capital outlay may not exceed £20,000. If they commence with the installation at the Town Hall and Public Library a capital outlay of £2,500 would be sufficient.

GLASGOW.—At a meeting of the Tramways Committee of the Corporation on Wednesday the methods of mechanical tramway traction which the Committee had witnessed during their recent visits to Bristol, Coventry, and places on the Continent, were discussed, and it was decided to recommend the Corporation to adopt the overhead electric system, the cars to be provided with seats on top.——The City Fathers are much exercised over what is called the "disgracefully-lighted condition of the streets," and it has been decided to instruct the Watching and Lighting Committee to consider the matter, and report at an early date. Mr. Primrose said his Committee had been considering how to improve matters, and they recognised that the operations of the near future in connection with the tramway service and the improvement of the electric light system would probably deal with the principal thoroughfares, but the subsidiary streets would have to be lighted by gas lamps for some years to come, and for that reason he would like to see them a great deal better illuminated than they were at present. The gas bill for the present year was undoubtedly a heavy one, but he thought there should be a lower rate for the supply of gas for street lighting than for private. He held that the financial position of the Gas Committee was unsound.

HALIFAX.—The electric light has been installed at the Belle Vue Public Library. The work has been carried out under the superintendence of the borough electrical engineer (Mr. T. P. Wilmshurst). About 110 incandescents are employed.

HALIFAX.—The Gas Committee of the Halifax Corporation hold an exhibition of electrical appliances in the Northgate Hall in about a fortnight's time, to include electric motors suitable for small tradesmen and electric heating and cooking appliances.

HOSPITAL LIGHTING.—The Borough Electrical Engineer of Glasgow is preparing plans and specifications for the electric lighting of Ruchill Hospital. Current is to be obtained from an independent plant.——It has been decided to introduce the electric light into the Devon and Exeter Hospital at a cost of about £1,200. The annual upkeep expenses are put at £190, or £50 less than the sum at present paid for gas.

KILLARNEY.—At Killarney Petty Sessions on Tuesday a number of summonses arising out of the surcharging of four members (Messrs. J. Duckett, D. O'Sullivan, J. Kelly, and D. Hurley) of the Town Commission with the sum of £85. 2s. 3d. in connection with the electric lighting of the town, were down for hearing. The defendants having failed to comply with the order to pay the amount to the credit of the Town Commissioners' account the present proceedings were instituted by the auditor, Mr. Calvert. It will be remembered that in 1893 the Commissioners entered into a contract for the lighting of the town by gas, but after the elections in October, as there was a majority in favour of the electric light another contract was entered into with the Killarney Electric Lighting Company for lighting the town by electricity. The gas contractor continued to fulfil his contract, while the Electric Lighting Company put in an installation for lighting the streets electrically, and various cheques were passed by the Commissioners in favour of both contractors. The auditor, however, held that the gas contract being in existence, it could not be set aside by the Commissioners, and decided that the resolution revoking it and consequently the contract with the Electric Company was invalid. As the defendants have applied to the Queen's Bench Division for the purpose of having the auditor's order quashed the hearing of the summonses was adjourned.

LAMBETH (LONDON).—After a discussion extending over three evenings the Vestry have finally decided by 44 votes to 15 to adopt the recommendation of the Electric Lighting Committee to transfer their Provisional Electric Lighting Order to Mr. C. W. SAX.

LIVERPOOL.—The City Council have consented to the application of the National Telephone Company to lay their telephone wires underground.

LURGAN (IRELAND).—A proposal for the lighting of the streets by electricity has been submitted to the Town Commissioners, and is at present under consideration.

MANCHESTER.—For the purpose of extending the electric lighting plant, mains, &c., the Town Council have decided to apply to the Local Government for sanction to borrow an additional sum of £100,000. It was explained that this large amount was required in order to keep pace with the increasing demand for the electric light.

MILL LIGHTING.—The electric light is being extensively employed for mill lighting in India, one of the latest installations being that at the mills of the Marajee Goculdas Spinning and Weaving Company, at Parel, Bombay. Messrs. Nowrosjee Wadia and Sons, of Tardeo, Bombay, were the contractors.

NEWINGTON (LONDON).—The refusal of the Board of Trade to accede the Vestry's application for a Provisional Order was discussed at the last meeting, and it was decided to oppose any future application by a company for a Provisional Order.

NEWPORT (MON.).—The provision market is now lighted electrically by means of 2 arcs and about 250 incandescents.

OXFORD.—It has been decided to considerably increase the generating power at the station of the Oxford Electric Company, and on the advice of the Company's engineer, Mr. J. Hardie McLean, orders have been placed with Messrs. J. and H. McLaren for a 500 I.H.P. triple expansion surface condensing engine, and with the Electric Construction Company for a 260-kilowatt machine. Up to the present 100 and 80 unit machines have been used. The makers' guarantee is calculated to maintain the economy in working for which the Oxford station possesses a good record. The capacity of the plant will be raised from an equivalent of 19,000 to 33,500 8 c.p. incandescents connected.

PARLIAMENTARY.—In the House of Commons on Monday last the Chairman of Ways and Means (Mr. J. W. Lowther) moved the suspension of Standing Order 171 for the remainder of the Session. He explained that this Standing Order prevented corporations from working their own tramways. The Grand Committee on Trade had recently passed the third clause of the Light Railways Bill, which gave corporations, county councils and district councils power to construct and work their own light railways, and in view of that decision no case could be made out for preventing corporations from working their own tramways, and various corporations had Bills before Parliament asking for leave to work tramways. The motion was agreed to.

——— In the House of Commons yesterday Mr. Ritchie, in reply to a question from Sir J. Leng, calling attention to the sug-

Digitized by Google

gestion made by Lord Justice Kay in a recent patent trial, that it was desirable there should be some functionary holding in relation to patents, a position analogous to that of the Comptroller in relation to trade marks, stated that the subject had engaged the attention of Parliament on and off for some years, and that the Bill of 1885 made some provision in this direction. It would, however, require so large a staff to report on the novelty or otherwise of patents that the Board of Trade were not in a position to make any recommendation on the subject.

PETERBOROUGH.—A Local Government Board inquiry was held at Peterborough on Wednesday into the application of the Town for leave to borrow £20,000 for the purpose of establishing Council electricity supply works in the town. The Council were represented by Mr. W. Mellows (town clerk), Mr. J. C. Gill (borough engineer), Prof. J. A. Fleming (consulting electrical engineer), and Mr. J. W. Walshaw (borough surveyor). Mr. H. Percival, barrister, appeared for the opponents. The Great Northern Railway Company, who are large ratepayers, were separately represented, and also opposed the scheme. The Town Clerk having given particulars of the application and of the financial condition of the borough, Prof. Fleming gave technical details of the scheme, and described the system proposed to be adopted, which he said had been successfully introduced in other towns. The ground of opposition was that the scheme would not prove a financial success.

STOCKPORT.—At the meeting of the Town Council, on Wednesday last, the Gas Committee recommended that £43,000 be voted for gasworks extensions. Alderman W. Atherton urged the Council to make an effort to introduce the electric light, as he understood several tradesmen would be willing to take electric current if it were available. The Chairman of the Gas Committee (Mr. T. Webb) gave the result of some inquiries he had made as to the success of the electric light at Manchester and Huddersfield, and stated that "he had not yet found any system of electric lighting which he could recommend as likely to be financially successful"! This is another case where (as at Stockton, &c.) the electric light clashes with the gas interest—which is in possession.

STOCKTON-ON-TEES.—The Town Council have at length decided to make a move in electric lighting matters. Application is to be made to the Local Government Board for sanction to borrow £18,000 for electricity supply purposes.

STORES LIGHTING.—The central stores of the Great Horton (near Bradford) Industrial Society are to be lighted electrically.

ST. HELENS.—The salary of the gas manager (Mr. S. Glover), who is to have the superintendence of the new electricity works, has been increased from £400 to £450.

ST. PANCRAS (LONDON).—The Electricity and Public Lighting Department of the Vestry have just presented their statement of accounts in respect of the Regent's Park station for the year 1895. The accounts are of a most satisfactory character, and prove that the department continues to make excellent progress. The total capital expenditure amounted to £113,889. 2s. 1d., an increase of £4,522. 18s. 4d., mainly caused by extensions of mains, services to consumers' premises, meters and switches. The total revenue amounted to £18,921. 17s. 5d., a net increase of £1,990. 0s. 10d., but as the charge for public lighting for the year showed a reduction of £857. 7s. 4d., the actual increase from private consumers amounted to £2,847. 8s. 2d., or nearly 23 per cent. increase. The total generating expenses amounted to £6,737. 14s. 5d., an increase of £561. 4s. 6d. There was an increase of £1,623. 13s. 11d. in the distribution expenses, this large increase being chiefly attributable to the necessity of replacing the whole of the insulators and bearers in the manholes in consequence of the explosions in culverts that occurred early in the year. Nearly £600 was paid for this work, in addition to a sum of £300 for extra staff employed in cleaning the incrustation off the old insulators and other work during the time the new insulators were being put in. After providing for the whole of these expenses there remained a profit of £6,575. 15s. 4d. (equivalent to nearly 6 per cent. on the capital expenditure) to meet repayments, interest, &c., which absorb £5,640. 10s. 9d., leaving a net profit of £935. 4s. 7d. This sum, added to the balance on last year's accounts of £1,768. 6s. 7d. (less £554. 4s. 7d. written off for preliminary expenses), leaves a net balance of £2,149. 6s. 7d. to be carried forward. The yearly progress of the station since the commencement of supply is shown by the following table :—

| Dec. | No. of consumers. | Current sold to private consumers. | | No. of lamps, &c., applied for. | | |
|---|---|---|---|---|---|---|
| | | 3d. per unit. | 6d. per unit. | Incandescent, 16 c.p. | Arc. | Motors. |
| 1892 | 172 | ... | £8.167 7 8 | 9.990 | 82 | 11 |
| 1893 | 238 | £384 11 6 | 9.161 6 0 | 12.851 | 110 | 19 |
| 1894 | 349 | 1,236 13 9 | 10.819 15 0 | 15,532 | 129 | 22 |
| 1895 | 447 | 2,142 9 6 | 12,682 6 0 | 19,195 | 139 | 37 |

TELEPHONE EXTENSION IN THE HIGHLANDS.—The Post Office have decided to erect a trunk telephone line between Aberdeen, Elgin and Inverness.

WALSALL.—The Town Council will consider, at their next meeting, a resolution in favour of the purchase of the tramway lines within the borough.

WELLS.—Mr. J. A. Tate has given notice that he will move at the next meeting of the City Council "That plans and specifications be at once prepared for an electric light installation."

WORCESTER.—A Local Government Board inquiry was held at Worcester on Tuesday last into the application of the Council for sanction to borrow £6,580 for electric lighting purposes. The Town Clerk (Mr. S. Southall) gave particulars of the application, and stated that the present loan was required for the extension of the mains and additional lamps.

YORK.—The greater part of the last sitting of the City Council was devoted to a discussion on the electric lighting question. Mr. Lambert moved the recission of the resolution passed in May, 1892, whereby the Council decided to keep the electric light in their own hands. He made a lengthy speech in support of this motion, and quoted various figures from the returns of electric supply undertakings, recently published in *The Electrician*. Mr. Purnell delivered an able speech in opposition, and the motion was lost by 9 votes to 17.

ELECTRO-HARMONIC SOCIETY.—The balance sheet of this Society is to be presented at the annual general meeting to be held on Friday next at the Institution of Electrical Engineers, 28, Victoria-street, London, S.W. During the past season 35 new members have been presented, 30 have resigned, eight have been struck off the register, and the Society has lost two members by death. There are now 300 members. The balance sheet, subject to audit, shows a credit balance forward of £95. 14s. 1d., against £73. 15s. 8d. for last year.

# PATENT RECORD.

*A record of Applications for Patents and Patent Specifications Publishe is compiled for this journal by* MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

## APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

April 18, 1896.

8,169. P. MEYER. London. Electric lighter for incandescent gas lamps. [Date applied for under Patents, &c., Act, 1883, Sec. 103, September 20, 1895, being date of application in United States.]

8,185. P. C. EBBUTT. Birmingham. An improvement or improvements in the method of raising or lowering electric light fittings, gas fittings, and the like.

8,203. J. ROW. Manchester. A new or improved make of housing or troughing for electric wires.

8,210. H. J. FISHER. London. Improvements in means for automatically controlling the carbon feed in electric arc lamps.*

8,216. W. E. GRAY. London. Improvements in electric motors and dynamos.

8,228. SIEMENS BROS. AND CO. (LIMITED) and E. F. H. H. LAUCKERT. London. Improvements in armatures for electric generators or motors.*

April 20, 1896.

8,262. M. COMMICHAU. Saxony. Apparatus for fastening and tightening wires for electric streams to insulators by means of a lever.

8,269. G. WILKINSON. London. An improved system of running and insulating concentric electrical conductors and appliances in connection therewith.

8,271. W. S. BOULT. London. Improvements in or relating to electric traction.

8,308. V. A. FYNN. London. Improvements in or connected with electrical resistances.

April 21, 1896.

8,316. E. H. WRIGHT, J. J. HECKMAN, A. H. GRAVES, C. C. CARNAHAN, and W. H. CARNAHAN. London. Improvements in electric switches.*

8,320. G. FABBRO. London. Support or bearing for electrical accumulators or other apparatus, having for its object the minimising of vibration.

8,338. W. E. KENWAY. Birmingham. Improvements in the mode of connecting the car with the overhead wire in tramways worked by electricity.

8,362. E. J. DEVINE. London. Improvements in and relating to electric signalling devices between cars of railway trains.

10,614. SLOPER and BECKETT. Electric telephone systems.
10,687. GOULD. Arc lamps.
11,016. BLACKMAN. Electrolytic decompositions, &c.
11,025. SIEMENS BROS. AND CO., LIMITED (Siemens and Halske). Electrically working railway switches and signals.
11,032. EREMIN. Secondary batteries.
15,114. ERBEN and BERGMANN. Electric current meters.
19,304. WISE (Moore Electrical Company). Producing electric light.
20,801. VON MORSTEIN. Electrically lighting gas jets.
20,924. THOMPSON (Higgins). Electric annunciators.

1895.

2,915. CZARNIKOW. Electric gas igniting and extinguishing apparatus.
4,076. THOMPSON (Porzellanfabrik Kahla, Filiale, Hermsdorf-Kloster lausnitz). Incandescent electric lamp holder.
4,238. DEVONSHIRE (Knight). Dynamo electric machines and motors.

# COMPANIES' MEETINGS AND REPORTS.

## Submarine Cables Trust.

The twenty-fifth ordinary annual meeting of the certificate holders in the Submarine Cables Trust was held at the offices, Winchester House, Old Broad-street, on the 1st inst., the Marquis of Tweeddale presiding.

The SECRETARY (Mr. A. G. Brodrick) read the notice convening the meeting and the minutes of the last meeting, and the report of the Trustees was taken as read.

The CHAIRMAN: In asking you to adopt the report and accounts I cannot help referring to the absence of Sir John Pender, who has occupied the chair ever since this Trust was formed. I think I am the only one left now of those who were present when the Trust was originally established, and I am sure that the regret I express will be shared by everyone present and everyone connected with the Company, whether present or absent. The year on the whole has been a prosperous one for the Trust. The revenue for the past year amounted to £22,313, as against £21,464 in 1895, or an increase of £849. This increase is entirely due to our having received a larger dividend for the current year from our investment in the Anglo-American Telegraph Company. I hope we may look forward to a continuation of this increase in the Anglo-American Company's dividend, as their receipts are showing increases every day. The total expenses for the year amounted to £1,099, or a decrease compared with those of 1895 of £95. It will be seen with satisfaction on reference to the accounts that the cost of administering the Trust is £900 less than the amount provided by the trust deed. Our revenue for the past year, including the £224 brought forward from the previous year, has enabled us to pay the equivalent of two coupons of £3 each, and clear off an additional 5s. of the remaining portion of the overdue coupon. This still leaves a balance of £1 in arrear, which will be gradually paid off should the present income derived from our investments be maintained or increased in future. There is every reason to look forward to an increase which would very soon wipe out this amount in arrear. The present mean market value of the investments held by the Trust as compared with the cost price shows an appreciation of over 60 per cent. The 3,381 certificates remaining in the hands of investors are, therefore, worth on this basis about £164 each, whereas, I understand that their market price is about £130. I think this may be regarded as a very satisfactory feature in the position of our Trust. With these remarks I beg to move—

"*That the report and accounts of the trustees to April 15, 1896, submitted to this meeting, be and the same are hereby received and adopted.*"

Mr. J. DENISON PENDER: I second that.

The motion was carried unanimously.

Mr. SHUTER proposed the re-election of Messrs. Deloitte, Dever, Griffiths and Co., and Messrs. Cane, Jackson, and Jefferys as auditors of the Trust for the ensuing year.

Mr. BEDWELL seconded the motion.

Mr. LAMONT inquired whether two firms of auditors were wanted.

The SOLICITOR referred to the trust deed, and said he thought that it certainly contemplated two firms.

The CHAIRMAN: "Each of the auditors shall receive such payment not exceeding," &c. That clearly indicates that two auditors were contemplated. He then put the motion, which was carried unanimously.

Mr. ANSELL afterwards proposed, and Mr. SHUTER seconded, a vote of thanks to the Chairman and Trustees, which was carried unanimously.

The proceedings then terminated.

## China and Japan Telephone Company (Limited).

The thirteenth ordinary general meeting of this Company was held at the offices, 14, Austin-friars, London, on Tuesday, Henry Grewing, Esq., the Chairman of the Company, presiding.

The SECRETARY (Mr. Alex. B. Chalmers) read the notice calling the meeting and the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, you will see by the figures of the report that the Company has gone on doing an improving business during the past year, and we have every reason to hope that it will continue to do so. As you are aware, the sphere of operations of this Company is a rather limited one, but recent events in China have led the Government there to adopt a more liberal treatment towards foreign enterprises generally. I do not mean to say that this will benefit us directly, but it will certainly do so indirectly, because machinery, for instance, which has been prohibited from entering the country for many years, is now admitted freely, and consequently there are factories springing up all round, and wherever activity increases it means, of course, that our telephone will certainly be wanted. If figures speak for themselves, I cannot do better than mention the increase in the number of our subscribers compared with ten years ago. At the present moment we have something over 470 subscribers, while ten years ago we counted not more than about 100. That is a satisfactory increase. I take this opportunity of freely and fully acknowledging the services that have been rendered by our managers in China, and especially by Mr. Porter at Shanghai, where the greatest improvement and development of our business has taken place, and will most probably continue to take place in the future. I can assure you that your business will in the future be watched with the same interest and the same close attention as has been the case in the past. I have nothing further to add, and I beg to move—

"*That the Directors' report and the audited accounts for the year ended December 31, 1895, be and the same are hereby approved and adopted.*"

Mr. THOMAS LLOYD seconded the motion, which was carried.

Mr. THOMAS LLOYD then moved the re-election of Mr. Henry Grewing as a Director of the Company.

Mr. W. ADDISON seconded the motion, which was agreed to.

Messrs. Price, Waterhouse and Co. were re-elected auditors.

A sum of 200 guineas was voted to the Directors as remuneration for their services during the past year.

A vote of thanks to the Chairman and Directors closed the proceedings.

The Directors' report for the year ended December 31st last states that the profit and loss account, after charging debenture interest and bringing £361. 8s. 5d. from 1894, shows a credit balance of £1,295. 5s. 3d. £750 is placed to reserve, and £545. 5s. 3d. is carried forward. The result of the working of the exchanges for the past year, both at Shangai and Hong Kong, is satisfactory, and the income at both stations has been considerably increased at but small additional expense to revenue, although it has necessarily involved further capital outlay. The bond for £5,000, issued in 1891 to secure the debentures held by the Oriental Telephone and Electric Company (Limited), fell due on December 31, 1895, and has been extended for a further period of five years with the consent of that Company.

## Western and Brazilian Telegraph Company (Limited).

The following report of the Directors of this Company for the half-year to December 31st last will be presented at the general meeting to be held at Winchester House, London, E.C., on Thursday next, at twelve o'clock:—

The total earnings amount to £80,315. 2s. 10d., against £82,815. 11s. 11d., a decrease of £2,500. 9s. 1d. compared with the half-year to December 31, 1894. The working expenses amount to £38,122. 9s. 11d., against £36,403. 17s. 3d., an increase of £1,718. 12s. 8d. Including the amount brought forward (£5,803. 7s. 5d.), and the dividend received upon the shares held in the Platino Company, the balance to the credit of the revenue account is £52,614. 2s. 10d., from which has been deducted £11,148 for debenture interest and £7,952 for the debenture redemption fund, leaving £33,514. 2s. 10d., of which £3,000 has been placed to reserve. The Directors now recommend the payment of 5s. 3d. per share, free of income tax, for the half-year on the Ordinary shares, making, with the dividend paid in November last, £3 per cent. for the year, the same as paid for 1894, leaving a balance of £4,952. 13s. 7d. to be carried forward. In the case of shares which have been divided into Preferred and Deferred, the 5s. 3d. per share now recommended will be payable, viz., 3s. 9d. to the Preferred shareholders (making up the full dividend of £5 per cent. on these shares for the year 1895) and 1s. 6d. per share to the Deferred shareholders.

There is no change in the position of affairs between the Government of Brazil and the Company as to the purchase of the cables. The Directors have to report the sale of the ss. "Viking" to the Amazon Telegraph Company for £12,300; £1,329. 18s. 2d. had to be spent upon the vessel. After adding this to the amount the "Viking" stood at in the last accounts—viz., £8,500—there remained a balance of profit of £2,470 1s. 10d., which amount the Directors have applied in reduction of "Norseman" No. 1; and as, since the close of the year, the vessel has been sold at a loss, they have written this off against the reserve fund. In the accounts for the current half-year the matter will be finally dealt with. "A" and "B" Debentures, amounting to £15,900, have been paid off at par. The dividend warrants will be posted on the 15th inst.

Lord Richard H. Browne and Mr. John Coppen will offer themselves for re-election as Directors, as will the auditors, Messrs. Turquand, Youngs, Bishop and Clarke.

## Brazilian Submarine Telegraph Company (Limited).

The following is the report of the Directors of this Company for the half-year ended December 31st last, to be submitted to the general meeting to be held at Winchester House, London, E.C., on Wednesday next, at 12 o'clock :—

The revenue amounted to £106,167. 13s., and the working expenses to £21,623. 7s. 3d. After providing £3,200 for debenture interest and sinking fund, and £1,705. 12s. 10d. for income tax, there remains a balance of £79,638. 12s. 11d., to which is added £4,410. 9s. 3d. brought forward from June 30th last, making £84,049. 2s. 2d. First and second interim dividends (amounting to £39,000) have been paid, and £30,000 transferred to reserve, leaving £15,049. 2s. 2d. to be carried forward. The receipts for the half-year include £1,500 dividend to June 30th last on the Company's shares in the African Direct Telegraph Company (Limited). The various sections of the Company's lines are in good working order.

## NEW COMPANIES, STATUTORY RETURNS, &c.

**ALDERLEY AND WILMSLOW ELECTRIC SUPPLY (LIMITED).**—This Company was registered on April 24th with a capital of £30,000, in £1 shares, to take over the Provisional Order of the Urban District Council to carry into effect an agreement made with the said Council, to carry on the business of electrical engineers and suppliers of electricity, and to construct, let, use and maintain telegraph and telephone lines. The first subscribers, with one share each, are :—F. B. Ross, A. Crewdson, C. Duckworth, A. Midgley, E. Agnew, J. Royle and P. Whyman. The first Directors are :—E. Agnew, A. Crewdson, F. B. Ross and William P. J. Fawcus.

**INTERNATIONAL IMPROVED ELECTRIC COMPANY, (LIMITED).**—This Company was registered on April 22nd with a nominal capital of £75,000 in £1 shares, to aquire the benefit of certain inventions relating to the manufacture of improved electric glow lamps, together with a process of the manufacture of same, and the letters patent granted to or to be granted in respect thereof; and also to enter into an agreement with Ferdinand Fanta, and to carry on the business of electrical engineers, manufacturers of, dealers in and agents for lamps, fittings, plant, &c. The first subscribers, with one share each, are :—G. W. Putman, W. F. Smith, electrician, W. R. McAthy, F. L. Koch, F. Royce. C. J. Hupfeld and W. Dunz.

**KNOEFERL-BONN DENTAL AND MANUFACTURING COMPANY (LIMITED).** This Company was registered on May 1st with a nominal capital of £10,000, in £1 shares, to acquire the business of a manufacturer of dental appliances and mechanical engineer carried on by F. Knoeferl at Bolsover-street, London, W., and also the business of an electrical engineer formerly carried on by Jacob Bonn under the style of "J. Bonn and Co.," at Holborn-place, London, W.C., but recently purchased by the said F. Knoeferl, to carry on the business of manufacturers, dealers in and repairers of mathematical, scientific and dental appliances and apparatus, electricians, electrical and mechanical engineers, machinists, wire drawers, &c. The first subscribers, with one share each, are G. Gibbs, S. B. Saunders, J. H. Gartrell, Jacob Bonn, electrical engineer, F. Knoeferl, engineer, J. H. Greenwood, and E. A. Robinson.

**PERFECTA SEAMLESS STEEL TUBE COMPANY (LIMITED).**—This Company was registered on May 4th with a capital of £145,000, in £1 shares, to acquire the business carried on at Birmingham, under the style of "The Perfecta Seamless Steel Tube Company," and to carry on the business of mechanical engineers, wire drawers, tube makers, electro-platers, &c.

---

**APOSTOLOFF AUTOMATIC TELEPHONE PARENT SYNDICATE (LIMITED).** The statutory return to March 26th has been filed. The whole capital of £10,000, in £1 shares, has been taken up, and 6,500 have been issued as fully paid. The full amount has been called and paid on 2,100, but no calls have as yet been made on the remainder.

**I.E.S. ACCUMULATOR COMPANY (LIMITED).**—The statutory return to December 20th was not filed until April 11th. Out of a nominal capital of £100,000, in £1 shares, 50,000 have been issued as fully paid.

**KAMM'S ZEROGRAPH SYNDICATE (LIMITED).**—The statutory return to March 23rd has been filed. The nominal capital is £24,000, in £10 shares. 840 shares have been taken up, and 800 of these have been issued as fully paid to Mr. Leo Kamm. The full amount has been called on the remainder.

**MADEIRA ELECTRIC LIGHTING COMPANY (LIMITED).**—An agreement has just been entered into with Messrs. Ullathorne and Hartley, electrical engineers, Bradford, for the acquisition of a concession for the electric lighting of Funchal, Madeira. This consideration for the transfer, together with a complete electric lighting plant, is £33,000, stated to be satisfied as to £6,000 thereof by the allotment of fully paid shares, Nos. 1,801 to 7,800 inclusive.

**MEXICAN GAS AND ELECTRIC LIGHT COMPANY (LIMITED).**—The annual return to January 6th has only just been filed. The nominal capital of £100,000, in £20 shares, has been taken up, and all have been issued as fully paid.

**NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY COMPANY (LIMITED).**—The annual return to January 28th has just been filed. The nominal capital is £50,000, in £5 shares, of which 9,126 have been taken up, and 168 issued as fully paid; £4 per share has been called on 8,108, and £2 per share on the remaining 850.

**OGMORE VALLEY ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).**—The annual return to April 14th has been filed. Of a nominal capital of £10,000, in £5 shares, 710 have been taken up, and the full amount has been called.

**PONTYPRIDD ELECTRIC LIGHTING AND POWER COMPANY (LIMITED).**—The annual return to April 10th has been filed. 1,143 shares have been taken up out of a nominal capital of £10,000, in £5 shares. The full amount has been called on 669, and £4 per share on the remaining 474.

## CITY NOTES.

**MEMORANDA.**—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 31d. per oz. (May 7th). Consols (2¾ per cent.) 111⅛—111⅛ for money, 111⅜—112 for account; 2½ per cent. 105¼—105⅜ (May 7th). Stock Exchange Settling Days: Consols, June 1st; Stocks and Shares Continuation Days, May 12th and 27th; Ticket Days, May 13th and 28th; Pay Days, May 14th and 29th; Mining Share Carry-over Days, May 11th and 26th.

**AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).**—A list will be found in our advertisement columns of 120 Debentures of £100 each, which have been drawn for payment at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, London, on July 1st next.

**CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).**—This Company invite applications for 12,000 Ordinary shares of £5 each, at a premium of £2 per share, payable: 10s. on application, £2. 10s. on allotment, £2 on October 1st, and £2 on January 1, 1897. The additional capital is required for the extension of the mains, for erecting and equipping a new generating station and for providing necessary sub-stations. The lists opened yesterday, and close to-day (Friday).

**CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).**—The revenue return of this Company for the quarter ended March, 1896, is as follows :—Sale of current for public lighting £3,161, against £3,191 in the corresponding quarter last year; private lighting, &c., £38,280, compared with £26,622; estimated revenue from other sources £750, against £340; total—£42,191, compared with £30,153, an increase of £12,038. There was an equivalent of 8 c.p. lamps connected on March 25, 1896, of 207,268, an increase of 11,951 during the quarter, compared with 13,134 last year.

**CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).**—The traffic returns of this Company for the week ended May 3rd were £878, against £864 in the corresponding week of 1895, an increase of £14. The total receipts for the half-year amount to £17,027, against £16,983 for the corresponding period of 1895, an increase of £44.

**DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).**—The estimated traffic receipts of this Company for the month of April are £2,422.

**EASTERN TELEGRAPH COMPANY (LIMITED).**—This Company's traffic receipts for the month of April amounted to £72,824, against £67,046 in the corresponding period last year.

**EASTERN EXTENSION AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).**—The traffic receipts of this Company for the month of April, amounted to £47,436, against £38,C80 in the corresponding period of 1895.

**GENERAL ELECTRIC COMPANY OF AMERICA.**—In a supplement particulars are given by the *Electrical Engineer* of New York of the year's transactions of the General Electric Company. The sales show a figure of about 12¾ million dollars. The annual report of the president, Mr. C. A. Coffin, states that the business of the year, including royalties, amounted to $13,315,667, against cost of goods and all other expenses and taxes $11,759,857, a credit surplus of $1,555,810., less interest on debentures, sundry losses, depreciation and other charges, bringing the balance down to $1,388,967, from which $511,322 is written off plant, patents, &c., leaving a net balance of $877,645. Since the closing of the fiscal year a contract has been completed with the Westinghouse Electric and Manufacturing Company which embodies a recognition of the patents of each company by the other, and the right, subject to certain exclusions, to a joint use thereof. A number of valuable patents have been acquired by the Company during the year. The revenue derived from interest and dividends was found nearly sufficient to provide for the interest on the Company's outstanding debentures.

**GREAT NORTHERN TELEGRAPH COMPANY.**—The traffic returns of this Company in April, 1896, were £23,200, and the total receipts from January 1st to April 30th £90,000, against £83,000 and £95,600 in the corresponding months of 1894 and 1895 respectively.

**LIVERPOOL GAS FITTINGS COMPANY (LIMITED).**—The annual general meeting of this Company was held on Wednesday last, Mr. J. B. Smith presiding. In moving the adoption of the report and accounts, the Chairman said that the profit on the past year's working amounted to £1,637, against £1,576 last year. During the year they had taken up agencies, which he thought would be of considerable benefit to the Company. In consequence of the increase in their business more capital was required, and the Directors proposed to issue Four per Cent. Debentures to the extent of £4,000 for a period of 10 years, redeemable at three years on six months' notice. The motion was adopted, and a dividend at the rate of 10 per cent. was declared. It has been decided to alter the name of the Company to the Liverpool Gas and Electric Fittings Company (Limited).

**LIVERPOOL OVERHEAD RAILWAY COMPANY.**—The traffic receipts of this railway for the week ended 3rd inst. amounted to £1,145. The amount for the corresponding week last year was £1,148. Decrease £3.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).**—This Company's traffic receipts for the week ended May 1st, after deducting 17 per cent of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,583.

**WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).**—The estimated traffic receipts of this Company for the half-month ended April 30th are £2,776, against £2,656 in the corresponding period of 1895

# TRANSFORMERS

## 30,000 H.P. SUPPLIED.

The BRUSH ELECTRICAL ENGINEERING COMPANY'S Transformers are the outcome of many years' Manufacturing Experience, and embody the highest possible qualities of

## EFFICIENCY, REGULATION AND RELIABILITY.

SPECIAL TERMS for LARGE ORDERS or for YEARLY CONTRACTS.

FOR ALL PARTICULARS APPLY TO—

## THE BRUSH ELECTRICAL ENGINEERING CO., Ltd.,

49, QUEEN VICTORIA STREET, LONDON, E.C.

## UNDERGROUND MAINS.

## CALLENDER'S BITUMEN TELEGRAPH & WATERPROOF COMPANY, Ltd.

MANUFACTURERS OF

### ELECTRIC LIGHT CABLES, MAINS, CONDUITS AND ACCESSORIES.

**Engineers and Contractors. Ironfounders and Coppersmiths. Makers of Lead Tube and Pipes. Bitumen Refiners**

**Head Office: 90, CANNON STREET, LONDON, E.C.**

Telephone No. 15133. Telegraph Address: "CALLENDER LONDON."

**Factory—ERITH MARSHES, KENT.**

**LIVERPOOL—Oldham Place, Renshaw Street. BIRMINGHAM—58, Water Street.**

**NOTTINGHAM—King John's Chambers, Bridlesmith Gate. GLASGOW—Great Western Road, Kelvinside.**

Also Contractors for underground Mains at ABERDEEN, COATBRIDGE, BURNLEY, LANCASTER, HUDDERSFIELD, SHEFFIELD, HULL, OXFORD HANLEY, CHELSEA, &c., &c.

The CALLENDER COMPANY is prepared to undertake the laying of Underground Mains, including all excavation and reinstatement of paving, building boxes, feeder points, or transformer chambers, erecting lamp posts, pillars and all other accessories required for the complete equipment of the distribution network of a Central Station, for either HIGH or LOW TENSION with CONTINUOUS or ALTERNATING CURRENTS —

1. With Vulcanised Bitumen Cables laid solid in Bitumen.
2. Or Drawn into CALLENDER-WEBBER or CALLENDER-RAWORTH Conduits, or into Pipes.
3. With Lead-Sheathed Cables, either Single Conductor, Concentric, or Triple Concentric, armoured and laid direct in the earth.

**Price 1s., post free 1s. 3d. Annual Subscription, 12s. 6d. post free, abroad 14s.**

## "THE ENGINEERING MAGAZINE:"

An American Monthly Periodical, having an extensive sale and containing popularly-written critical articles on Electrical Engineering and Social Subjects by leading writers.

**CONTENTS OF THE MAY ISSUE (No. 2, Vol. XI.).**

THE PRESENT VALUE AND PURCHASING POWER OF GOLD—H. M. Chance.
QUACKERY IN ENGINEERING EDUCATION—Edgar Kidwell.
THE VAST IMPORTANCE OF THE COKE INDUSTRY—John Fulton.
DEVELOPMENT OF ELECTRIC LIGHTING ENGINES—H. Lindley.
ARE BRITISH RAILROAD STOCKS GOOD INVESTMENTS?—Thos. F. Woodlock.
ELECTRICITY AND THE HORSELESS CARRIAGE PROBLEM—W. Baxter, jun
POINTS IN THE SELECTION OF STEAM ENGINES—W. H. Wakeman.
MODERN MACHINE SHOP ECONOMICS. II.—Horace L. Arnold.
MINOR MINERAL PRODUCTS OF THE UNITED STATES. I.—David T. Day.
RESTRAINTS UPON THE PRACTICE OF ARCHITECTURE—J. B. Robinson.

Each issue of the Magazine also contains—

**A Complete Index of the Contents of the World's Technical Press.**

THE ENGINEERING MAGAZINE is profusely illustrated and forms a handsome six-monthly volume. A complete Index to the Contents of the Magazine from the Commencement will be forwarded post free on request.

**A Specimen Back Number will be forwarded on receipt of 6d. to defray postage, &c.**

## TENDERS INVITED.

### VESTRY OF HAMMERSMITH.

ELECTRIC LIGHTING.

CABLES, ARC LAMPS AND POSTS, TRANSFORMERS.

The VESTRY of HAMMERSMITH are prepared to receive TENDERS for the following:—

(a) The SUPPLYING and LAYING of HIGH PRESSURE and LOW PRESSURE CABLES and PIPES.

(b) The SUPPLY and ERECTION of ARC LAMPS and LAMP POSTS.

(c) The SUPPLY and ERECTION of TRANSFORMERS and SUB-STATION EQUIPMENT.

(d) The SUPPLY and ERECTION of a 5 Ton OVERHEAD TRAVELLING CRANE.

Specifications, general conditions and form of tender can be obtained at the office of Mr. A. H. Preece, A.M.I C.E., 39, Victoria-street, Westminster. Applications for any one or all of the above sections must be accompanied by a cheque for two guineas, which will be refunded on receipt of a bona fide tender.

Sealed tenders endorsed "Cables," "Arc Lamps," "Transformers," or "Crane," must be delivered at the Offices of the Vestry, 57, Fulham Palace-road, Hammersmith, not later than noon on WEDNESDAY, 27th May, 1896.

The Vestry does not bind itself to accept the lowest or any tender.

W. P. COCKBURN, Vestry Clerk.

Vestry Offices,
57, Fulham Palace-road, W.

### THE METROPOLITAN ELECTRIC SUPPLY CO., LTD.,

offer the following

**WESTINGHOUSE ENGINES FOR SALE,**

owing to extensions and increase of H.P. required for larger Units.

All the Engines are in good condition and complete in all respects.

FIVE COMPOUND VERTICAL ENCLOSED ENGINES, each capable of indicating 320 H.P. when running at a speed of 250 revs. per minute, with a boiler pressure of 150 lbs. per square inch.

FIVE COMPOUND VERTICAL ENCLOSED ENGINES, each capable of indicating 250 H.P. when running at 280 revs. per minute, with a boiler pressure of 150 lbs. per square inch.

ONE COMPOUND VERTICAL ENCLOSED ENGINE capable of indicating 85 H.P. when running at a speed of 320 revs. per minute, with a boiler pressure of 150 lbs. per square inch.

The whole of the above Engines are fitted with variable expansion gear controlled by flywheel governors.

Permits to inspect may be obtained by application to the ENGINEER at 17, South-street, Manchester-square, W., who will give any further particulars.

### CITY AND GUILDS OF LONDON INSTITUTE,

SESSION 1896-97.

THE COURSES OF INSTRUCTION IN ENGINEERING AND CHEMISTRY at the Institute's Colleges commence in October, and cover a period of two to three years. The MATRICULATION EXAMINATION of the **Central Technical College** will be held on September 21st to 24th and the ENTRANCE EXAMINATION of the Day Department of the **Technical College, Finsbury,** on September 22nd.

**CITY AND GUILDS CENTRAL TECHNICAL COLLEGE**

(Exhibition-road, S.W.), a College for Higher Technical Instruction for Students not under 16 years of age preparing to become Civil, Mechanical or Electrical Engineers, Chemical and other Manufacturers, and Teachers.

THE MATRICULATION EXAMINATION will be held on September 21st to 24th, and the new Session will commence on October 1st.

Professors:—O. Henrici, LL.D., F.R.S. (Mathematics); W. C. Unwin, F.R.S., M.I.C.E. (Civil and Mechanical Engineering); W. E. Ayrton, F.R.S. (Physics and Electrical Engineering); H. E. Armstrong, Ph.D., F.R.S. (Chemistry).

**CITY AND GUILDS TECHNICAL COLLEGE, FINSBURY**

(Leonard-street, City-road, E.C.). The DAY DEPARTMENT provides Courses of Intermediate Instruction for Students not under 14 years of age, preparing to enter Mechanical or Electrical Engineering and Chemical Industries.

THE ENTRANCE EXAMINATION will be held on September 22nd, and the new Session will commence on October 6th.

Professors:—S. P. Thompson, D.Sc., F.R.S. (Electrical Engineering); J. Perry, D.Sc., F.R.S. (Mechanical Engineering); R. Meldola, F.R.S. (Chemistry).

JOHN WATNEY, Hon. Secretary.

City and Guilds of London Institute,
Gresham College, Basinghall-street, E.C.

### THE BRITISH ELECTRIC TRACTION (PIONEER) CO.,

LIMITED.

**1 and 2, GREAT WINCHESTER STREET, LONDON, E.C.**

*Chairman*—Sir CHARLES RIVERS WILSON, G.C.M.G., C.B.

This Company has been formed to DEVELOP ELECTRIC TRACTION in the United Kingdom and elsewhere, on the most approved methods and according to the requirements of each locality.

Address communications to E. GARCKE, Managing Director

**STANLEY**

## APPOINTMENTS VACANT.

### METROPOLITAN POLICE OFFICE,

NEW SCOTLAND YARD.

WANTED, a thoroughly competent ENGINEER to take charge of and work the Electric Light Installation. Applicants must be between 30 and 40 years of age, and be capable of managing a large generating plant. They must also be competent mechanics thoroughly capable of executing all ordinary repairs. Applications must be made in writing to the RECEIVER for the Metropolitan Police District, New Scotland Yard, S.W., and must contain full particulars of previous service and qualifications. The wages will be 50s. a week, rising to 60s., and the person appointed will be required to give his whole time to the work.

8th May, 1896.

### NORTHERN POLYTECHNIC INSTITUTE.

THE GOVERNORS invite APPLICATIONS for the appointment of HEAD of the DEPARTMENT of PHYSICS and ELECTRICAL ENGINEERING; commencing salary £250 per annum.

The appointment will date from September 29th, 1896, but the candidate appointed will be expected in the meantime to consult with the Principal as to the equipment and organisation of the Department.

Conditions of appointment, and forms of application, may be obtained from the Secretary, at the Institute, Holloway-road, London, N.

Applications, accompanied by copies of recent testimonials and the names of three referees, to be sent in to the PRINCIPAL, not later than June 1st, 1896.

E. GRIFFITHS, Secretary.

### COUNTY BOROUGH OF SALFORD.

MUNICIPAL TECHNICAL INSTITUTE.

The following APPOINTMENTS are about to be made, viz.:—

CHIEF LECTURER in CHEMISTRY, salary £200.
CHIEF LECTURER in DYEING, salary £150.
ART MASTER, salary £220.

Forms of application and particulars of duties may be obtained upon application to the SECRETARY at the Institute, Peel Park, Salford.

By order,

SAML. BROWN, Town Clerk.

Town Hall, Salford, 6th May, 1896.

### COUNTY BOROUGH OF SALFORD.

MUNICIPAL TECHNICAL INSTITUTE.

WANTED an INSTRUMENT MAKER, wages £2 per week. Forms of application and particulars of duties, &c., may be obtained from the SECRETARY at the Institute, Peel Park, Salford. By order,

SAML. BROWN, Town Clerk.

Town Hall, Salford, May 6, 1896.

## SITUATIONS VACANT AND WANTED.

A LEADING FIRM of Electrical Engineers and Contractors in London district requires the services of an ELECTRICAL ENGINEER in their estimating department. Reply stating experience, age and salary required, to:—"KENT," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ARMATURE WINDERS.—WANTED, six first-class men. Regular employment if suitable.—Apply, with testimonials, stating experience and wages required, P. R. JACKSON & CO., Ltd., Salford Rolling Mills, Manchester.

WANTED at once an experienced WIREMAN, permanency, must have good references.—Apply, Messrs. C. G. REED and SON, 26, North-street, Brighton.

ADVERTISER (nearly 16) wants to enter Electrical Engineering Works as PUPIL. Good references given and required.—Address, "MARTIN," 32, Silverlands-road, Silverhill, St. Leonards-on-Sea.

ELECTRICIAN (practical) wishes to canvass for and superintend electric light work, or as Traveller for accessories. Small salary and commission. Age 23.—"ELECTRICIAN," 21, Evesby-road, Kilburn, N.W.

ELECTRICAL ENGINEER, 6 years in electrical engineering works and 4 years installation work and its branches, could CANVASS and ESTIMATE.—"A. W.," 56, Demesne-road, Manchester.

PARTNER WANTED by experienced Electrical Engineering Manager with a valuable and large business connection. Capital required £2,000.—Apply, 2196, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ELECTRICIANS.—NOTICE to EMPLOYERS.—Please note we have a number of First-Class ELECTRICAL MEN upon our Books. Kindly send us particulars of any VACANCIES you may have. We can introduce you, free of charge, to the best men now at liberty.

Address, CHAS. RICHARDSON and CO., Engineers' Bureau 342, Strand, London, W.C

PARTNERSHIPS.—ELECTRICAL ENGINEERS and others WANTING PARTNERS, or wishing to SELL, can be introduced to Clients with Capital; and GENTLEMEN Seeking Investments can obtain personally (or through their solicitors) particulars of bona-fide OPENINGS. Strictest confidence observed.—Address, CHAS. RICHARDSON and CO., 342, Strand, London, W.C.

TO EMPLOYERS, COMPANY DIRECTORS, &c.

**THE LAW GUARANTEE & TRUST SOCIETY**

LIMITED,

**GUARANTEES FIDELITY.**

Send for Complete Prospectus, containing Balance-Sheet, Copy of Policy, &c., &c.

MORTGAGE, DEBENTURE, LICENSES AND CONTINGENCY INSURANCE.

Head Office: 49, CHANCERY LANE, LONDON, W.C.

**ELECTRIC LIGHTING AND POWER DISTRIBUTION.** An Elementary Manual on Electrical Engineering, suitable for Students preparing for the Prelimary and Ordinary Grade Examinations of the City and Guilds of London Institute. By W. PERREN MAYCOCK, M.I.E.E. Third Edition (in Two Volumes). Vol. I., with numerous Questions and Exercises, including all those set for the Preliminary and Ordinary Grade Examinations since 1890. 231 Illustrations, Index, and Ruled Pages for Notes.

CONDENSED TABLE OF CONTENTS OF VOLUME I.

CHAP. I.—Force, Mass, Work, Power, Energy, Units, &c.
CHAP. II.—Electricity, Conductance, Resistance, Quantity, Current, B. o. T. Unit, Circuit, Ohm's Law, Electrical Work and Power, Joule's Law, Heat Units, Condensers, &c.
CHAP. III.—Fall of Potential, Effects of a Current, Right-Hand Rules, Magnetism, Magnets for Direct and Alternating Currents, &c.
CHAP. IV.—Induction of Currents, Experiments in Electromagnetic Induction, Laws, Self and Mutual Induction, Attraction and Repulsion of Currents, &c.
CHAP. V.—Electric Bell Fitting, Indicators, Relays, Circuit Diagrams, &c.
CHAP. VI.—Magnetic Properties of Materials, the Magnetic Circuit, Curves, Measurement of H, M, I, B, and $\mu$, Susceptibility, Hysteresis, &c., &c.
CHAP. VII.—Board of Trade Standards, Measurement of Resistance, Wheatstone and Slide-Wire Bridges, Galvanometers, Voltmeters, Ammeters, Ohmmeters, Wattmeters, Recording Apparatus. The Measuring Instruments of Cardew, Ayrton and Perry, Holden, Kelvin, Swinburne, Evershed, Paterson and Cooper, Schuckert, Muirhead, Siemens, &c.
CHAP. VIII.—Principle of the Dynamo, Armatures, Armature Cores, Winding of Armatures, Field Magnets, Excitation, Sparking of Dynamos, Construction of Commutators, Rockers, Brush-Holders, Brushes, &c., &c.
CHAP. IX.—Direct-Current Dynamos. Illustrations and Descriptions of the Machines of Kapp, Mather and Platt, Siemens, Goolden, Laurence-Scott, Parker, Ernest Scott and Mountain, Joel, Crompton, Rankin-Kennedy, Lahmeyer, Brush, Mavor and Coulson, Jackson, Thomson-Houston; and Details thereof. # NOW READY, NEW EDITION.

# THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. VOL. I.

By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S., M.R.I., &c. FULLY ILLUSTRATED. PRICE 12s. 6d., POST FREE.

***Five Issues of the original Vol. I. were made and exhausted between September, 1889, and March, 1896.***

Since the issue of the First Edition of this work the study of the properties and applications of alternating electric currents has made enormous progress. . . . . The author has, accordingly, rewritten the greater part of the chapters, in the hope that the book will continue to be useful to the increasing numbers of those who are practically engaged in alternating-current work. Academic methods are avoided, and the necessities of the student who has to deal with the subject not as a basis for mathematical gymnastics but with the object of acquiring practically useful knowledge, have been fully considered.

**CHAPTER I.—Introductory.**

Faraday's Electrical Researches—Early Experiments on Electro-Magnetic Induction—Faraday's Ring Coil—Mutual Induction of Two Circuits—Faraday's Theories—The Induction of Electric Currents—Faraday's Lines of Force—Joseph Henry's Discoveries—The Production of Electric Currents by Magnets and Motion.

**CHAPTER II.—Electro-Magnetic Induction.**

Magnetic Force and Magnetic Fields—Definitions of Magnetic Quantities—Magnetic Force near Conductors—Typical Cases—Magneto-Motive Force and Magnetic Induction—Magnetic Potential—Tubes of Magnetic Induction—Faraday's Law of Induction—The Magnetic Circuit—Magnetic Resistance and Reluctance—Curves of Magnetisation—Determination of Permeability—Magnetic Hysteresis—Dissipation of Energy by Hysteresis—Variation of Hysteresis with Temperature.

**CHAPTER III.—The Theory of Simple Periodic Currents.**

Variable and Steady Flow—Current and Electromotive Force Curves—Simple Periodic Curves—Compound Periodic Curves—Fourier's Theorem—Mathematical Sketch of Fourier's Theorem—Analysis of Complex Curves—Simple Periodic Currents and Electromotive Forces—Mean-Square Value of a Periodic Current—Inductance and Inductive Circuits—Faraday's Experiments on Self-Induction—Electro-Magnetic Momentum—Coefficient of Self-Induction—Electro-Magnetic Energy—The Unit of Inductance—The Current Equation—Logarithmic Curves—Time Constant of a Circuit—Instantaneous Value of a Periodic Current—Graphic Representation of Periodic Currents—The Mean Value of the Power of a Periodic Current—The Theory of the Wattmeter—Impedance of Branched Circuits—Mutual Induction of Two Circuits—The Flow of Periodic Currents in Circuits having Capacity—Shunted Condenser in Series with Inductive Resistance—Representation of Periodic Currents by Polar Diagrams—Initial Conditions on Starting Currents in Inductive Circuits.

**CHAPTER IV.—Mutual and Self-Induction.**

The Researches of Joseph Henry—Mutual and Self-Induction—Induction at a Distance—Induced Currents of Higher Orders—Induction Effects by Transient Electric Currents—Theory of Induction Coil—Experimental Confirmations—Duration of Induced Currents—Magnetic Screening Action of Metallic Masses—Sonometer and Induction Balance—Transmission of Alternating Currents through Conductors—Prof. Hughes' Experiments—Distribution of Alternating Currents in Conductors—Electro-Magnetic Repulsion—Elihu Thomson's Experiments—Electro-Magnetic Rotations—Growth of Magnetic Induction in Magnetic Circuits—Symmetry of Current and Induction.

**CHAPTER V.—Dynamical Theory of Induction.**

Electro-Magnetic Theory—Electric Displacement—Maxwell's Theory—Displacement Currents and Displacement Waves—Mechanical Illustrations—Theory of Molecular Vortices—Comparison of Theory and Experiment—Velocity of Propagation of Electro-Magnetic Disturbances—Values of "v"—Vector Potential—Electrical Oscillation—Discharge of Leyden Jar—The Function of Condenser in the Induction Coil—The Alternative Path Experiments—Impulsive Impedance—Hertz's Researches—Resonance of Circuits—Interference Phenomena—Identity of Light and Electro-Magnetic Waves—Confirmatory Experiments—Experimental Determination of the Velocity of Propagation of Electro-Magnetic Waves—Recent Views.

**CHAPTER VI.—The Induction Coil and Transformer.**

General Description of the Action of the Transformer or Induction Coil—Experimental Determination of the Form of Current and Electromotive Force Curves—Curve Tracers—Discussion of Transformer Diagrams—Current and Electromotive Force Curves in Various Cases—Harmonic Analysis of Transformer Curves—Curves of Magnetic Induction—Power and Hysteresis Curves—Experimental Determination of Iron Arc Losses in Transformers—Practical Use of the Wattmeter—Efficiency Curves of Transformers—Secular Change in Hysteresis Loss in Transformers—Current Rushes into Transformers at Moment of Making Connection with the Circuit—General Theory of Transformer Action—The Power Factor—Importance of Large Power Factor—Open and Closed Circuit Transformers—Regulation and Secondary drop in Transformers—Magnetic Leakage—Control of Copper and Iron Losses in Transformers—Heat Radiation from Transformers—Transformer Specifications.

## PROSPECTUS.

OBJECTS OF THE COMPANY.—This Company was registered on 30th June, 1891, for the purpose of undertaking the supply of Electricity in the County of London, and elsewhere in the United Kingdom.

PREVIOUS ISSUES.—Of the authorised number of 40,000 Preference and 40,000 Ordinary Shares of £10 each, 10,000 Preference and 30,000 Ordinary Shares have been issued, of which the whole of the Preference and 22,475 Ordinary have been subscribed and called up.

PRESENT ISSUE.—The present issue of 10,000 Preference Shares is made in order to provide funds for the further development of the Company's business, and in allotting, applications received from registered holders of the existing Preference and Ordinary Shares of the Company will be preferentially considered.

FUTURE ISSUES.—It is not intended that the balance of 20,000 Preference Shares shall be issued except at a higher premium than that at which the present issue is offered.

CAPITAL EXPENDITURE.—The audited Balance Sheet of the Company at 31st December, 1895, shows Capital Expenditure as follows:—

| | |
|---|---|
| COUNTY OF LONDON STATIONS— | |
| Land, Buildings, Machinery, Plant, Mains, &c. .... | £137,065 3 9 |
| PROVINCIAL STATIONS— | |
| Investments in and Advances to Associated Electricity Supply Companies..... | 156,019 4 2 |
| | £293,084 7 11 |

This figure has been increased by expenditure incurred since the above-mentioned date.

REVENUE.—Dividends at the full rate of six per cent. per annum have been paid on the existing Preference Shares for the year ended the 31st December, 1895, and the Directors consider that the earnings of the Company during the present year will be sufficient to pay the dividend on the Preference Shares, including the present issue.

PARLIAMENTARY POWERS HELD BY THE COMPANY.—The Company holds Provisional Orders, confirmed by Acts of Parliament, for the following districts in the County of London:—

**The United Parish of St. James and St. John, Clerkenwell.**

**The Parish of St. Luke, Middlesex.**

**The District of the Wandsworth District Board of Works, including Parishes of Wandsworth, Putney, Clapham, Balham, Tooting, and Streatham.**

**The Parish of St. George the Martyr, Southwark.**

**The District of the St. Olave District Board of Works.**

COUNTY OF LONDON.—*St. Luke and Clerkenwell.*—In the St. Luke and Clerkenwell Districts the whole of the street work in the compulsory areas has been completed, and the station buildings are far advanced. Applications have been received for the equivalent of 7,000 8-c.p. lamps, of which 6,000 are connected to the Company's mains, and the Directors anticipate that there will be a sufficient number of lamps applied for by the time the station is completed, to ensure a profit being earned from the commencement of working the plant.

*Wandsworth.*—In the Wandsworth District the cables are being drawn in, the transformer sub-stations are in course of construction, and the generating station on the river Wandle is making rapid progress.

The plant now on order for the St. Luke and Clerkenwell and Wandsworth Stations will be capable of supplying 60,000 8 c.p. lamps, and the buildings for these stations will be sufficiently large to accommodate plant of more than double this capacity.

*Camberwell.*—The Company has applied to the Board of Trade for a Provisional Order for other areas in South London, and an Order has been granted for the Parish of Camberwell, subject to confirmation by Parliament.

PROVINCES.—In the Provinces the Company holds controlling interests in the following Electricity Supply undertakings:—

BOURNEMOUTH.—*The Bournemouth and District Electric Supply Company, Limited.*—The station buildings at Bournemouth have been remodelled and enlarged, and considerable extensions of mains have been carried out within the past year. The plant is capable of supplying 27,500 8 c.p. lamps, and connections equivalent to 21,000 8 c.p. lamps have been made.

DOVER.—*The Dover Electricity Supply Company, Limited.*—The Dover station was completed last year, and an uninterrupted supply of current has been given since April, 1895. The plant is capable of supplying 11,000 8 c.p. lamps, and 5,800 8 c.p. lamps are already connected.

RICHMOND, SURREY.—*The Richmond (Surrey) Electric Light and Power Company, Limited.*—Considerable extensions of mains have been made during the past year, and further extensions are now in progress. The plant is capable of supplying 9,500 8 c.p. lamps, and 5,900 are now connected.

CONTRACTS.—Particulars of the Contracts entered into at the time of the formation of the Company are given in the Prospectus dated 28th March, 1894, inviting subscriptions for the first issue of Ordinary Shares of the Company, copies of which Prospectus and of the Contracts therein specified can be seen at the Offices of the Company. Various other Contracts, relating to the business of the Company, have since been entered into. These are too numerous for particulars of them to be given but they can be seen at the Offices of the Company. Every person taking shares under this Prospectus shall be deemed to have had due notice of all such Contracts, and to have waived all rights to further particulars thereof, whether under section 38 of the Companies' Act, 1867, or otherwise. A Contract relating to the present issue, contained in letters dated respectively the 27th, 29th and 30th April, 1896, has been made between the Company and the Electric and General Investment Company, Limited, and the same can be seen at the Offices of the Company.

APPLICATION FOR SHARES.—Copies of the Memorandum and Articles of Association can be seen at the Offices of the Company and of the Electric and General Investment Company, Limited. Applications for Shares must be made on the form accompanying the prospectus and forwarded to the Bankers of the Company with the full amount of the deposit. If no allotment is made the deposit will be returned in full; and where the number of Shares allotted is less than that applied for, the available balance will be applied towards the payment due on allotment, and any excess returned to the applicant.

OFFICIAL QUOTATION.—The Preference and Ordinary Shares already subscribed are quoted in the Stock Exchange official list, and in due course application will be made to include the present issue in the quotation.

Prospectuses and Forms of Application can be obtained from the Bankers, the Brokers, the Electric and General Investment Company, Limited, and at the Offices of the Company.

*7th May*, 1896.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 939. [Vol. No. 3. XXXVII.] FRIDAY, MAY 15, 1896. PRICE SIXPENCE.

## NOTES.

THE Friday evening discourse on "Electric Shadows and Luminescence" delivered at the Royal Institution last week by Prof. SILVANUS THOMPSON was characterised by the prominence given to the vacuum-tube work which led up to the Würzburg professor's great discovery and by the scanty references made to the lecturer's own investigations. It will certainly not be the fault of Prof. THOMPSON if the English public remains opaque to the claims of CROOKES, MÜLLER of Frankfort, LENARD, WIEDEMANN, EBERT and other pre-Röntgenites. The following combination of properties was given as a "test" for X-rays:—(1) They cause phosphorescence; (2) they affect photographic plates; (3) they pass through aluminium; (4) they are *not* deflected by a magnet. This list of idiosyncracies also shows what a very narrow escape X-rays had from being cathode rays, their non-deflectability by a magnet alone differentiating them from the rays which LENARD has investigated so exhaustively.

THE discourse was, it is needless to say, illustrated by a bewildering wealth of experiments. As a good sample we may quote the following:—A sheet of ebonite was electrified, then electrostatically screened, and exposed to X-radiation. On dusting with the usual powdered mixture the discharging action of the rays was shown by the development as a dust-figure of the shadow of an object interposed between the X-ray source and ebonite plate.

WITH regard to Prof. THOMPSON'S own results, he has found that the diamond, although much more transparent than glass, is more opaque than block carbon or graphite. Again, in a Crookes tube he finds that one cannot (unless by a special arrangement just discovered) obtain two shadows of an object by employing two cathodes; whence it follows that *cathode* rays are not mere wave motion. The photographic action of a tube is improved by directing the cathode discharge upon a metal surface or upon an enamel containing lead. Heating the "anti-cathode" is also found to be an advantage. X-rays affect the brush discharge in air of a Wimshurst machine. Perhaps the most scientifically interesting discovery is that the transparency of materials to X-rays is more nearly proportional to their specific heats than to the reciprocal of their atomic weights as announced by Prof. DEWAR. Prof. THOMPSON also lighted upon the fact, unearthed in France by M. HENRY BECQUEREL, and first published by him in the *Comptes Rendus*, that bodies which emit visible rays when shone upon by X-rays emit X-rays when exposed to light.

WHEN, some time since, Prof. AYRTON suggested that if there was a back electromotive force in an electric arc the resistance ought, in certain conditions, to be negative, the not unnatural suggestion met with a good deal of ridicule. In a Paper on "The True Resistance of the Electric Arc," by Messrs. J. FRITH and J. RODGERS, read before the Physical Society last Friday, it was shown that when both the carbons are solid the ratio $d\,V/d\,C$—where V is the impressed voltage, and C the current in the arc—is always negative; while when cored carbons are used it is always positive. The authors of this Paper have called this ratio the true resistance of the arc, and certainly, if this definition is disputed, it is difficult to see what other ratio to settle upon. Obviously, to take the ratio of V to C would beg the whole question of a back electromotive force in the arc, and is quite inadmissible. Nor can we take the V – C curve back to the origin, since an arc is impossible over so wide a range. Nor, again, can we deal with any considerable amount of the possible curve, since every point on it corresponds to a *different* arc. The only resource is to take the rate of change of V with respect to C; and, oddly enough, this never was challenged so long as the result gave a positive value. It is only when the apparently anomalous "negative resistance" is the conclusion forced that any doubt seems to arise.

IT has been argued that a negative resistance is a physical impossibility. To this the authors of the Paper and Prof. AYRTON pertinently reply that so is the electric arc *solus* an impossibility. Mrs. AYRTON has shown that when a fixed potential difference is forced on the carbon ends there is a condition of instability in which a steady arc is impossible. Only when a certain amount of "steadying resistance," sufficient to over-balance the negative resistance of the arc itself, is placed in series with the arc, will the arc continuously and steadily exist. Apparently the corollary to a negative arc resistance is a back electromotive force. For, if the true resistance of the arc is wholly and really negative, the $C^2 R$ loss in overcoming it must also be negative. In other words the true resistance must *absorb* heat, by some obscure endothermic action. But there is a large amount of heat actually and positively generated in the arc, and since this is not generated in overcoming resistance, the only conceivable other way in which it can be developed is by a back electromotive force.

THERE is something very refreshing in the breeziness of the discussion on Mr. BARNETT's Paper on "The Evolution of the Storage Battery," of which we publish an abridged report this week. As far as possible the phraseology of the original has been retained, and condensation has been effected by omitting unnecessary repetitions and amplifications. After the more or less set debates to which we are accustomed at the Institution of Electrical Engineers, and the guarded tone usually adopted by the speakers, it is a distinctly novel sensation to see men thus fearlessly plunging into the troubled electrolytic waters of the lead cell. There is one point in the Paper which arrests attention at once, and that is, there are no curves. This is a distinct innovation, and one to be rather commended in this connection, for of curves we have had no end, but very little explanation as to the inward and chemical changes of which the physical phenomena are but the outward and visible sign. It is somewhat startling to be told that lead sulphate is an electrolyte, for it has always been considered an axiom in this country that an electrolyte must be a fluid, and further it is difficult to see how the current could pass from one cell to the other without electrolysing the acid, and we must believe in this impossibility if we are to accept LEIBENOW's hypothesis as propounded by Mr. REED. Lead sulphate is only sparingly soluble in sulphuric acid, and though in time the sulphate formed on the plates during discharge might be dissolved in the acid, this would result in the electrolysis of the lead sulphate solution, and not in the conversion of the sulphate on the plates into peroxide of lead and spongy lead respectively, and it is these latter reactions which occur in practice.

WITH regard to the discussion as to the electromotive force as determined from the heat-equivalents of the chemical reactions occurring in the cell, one of the objections to the sulphate theory has always been that on this hypothesis the calculated electromotive force works out a little below that observed in practice, and considerably below that of a briskly charged cell; but when one considers the difficulties involved in the determination of the heat of formation, it is unreasonable to expect an exact agreement between the calculated and observed electromotive forces. On the assumption that the sulphating of the plates which takes place during discharge is due to the abstraction of $SO_4$ from acid of the strength contained in the cell, the calculated electromotive force is usually given as about 1·98 volt, but if we assume that the $SO_4$ is taken from concentrated sulphuric acid, then we get an electromotive force considerably too high. The fact that the acid cools during discharge has considerable influence on the question, and appears to show that the formation of lead sulphate takes place, not at the expense of acid of the concentration next the material undergoing change, but at the expense of free molecules of $H_2SO_4$ present in the acid liquid, the withdrawal of which conditions the appearance of a fresh supply. Chemical energy, which appears as sensible heat, cannot also produce electrical energy, but this is a point which is often overlooked in discussing the chemistry of accumulators.

SOME doubt has also been cast, from time to time, on the identity of the electrolytic lead peroxide with that produced by active chemical process. Mr. DESMOND FITZGERALD has always urged that the former is some hydrated peroxide; and there are experiments on record which show that the electromotive force yielded by a couple formed between lead and ordinary peroxide is not so high as that yielded with electrolytic peroxide. But this may be due to the effect of the support in the former case, for it is well known that the effect of the latter must be eliminated by having a dense and adherent coating of lead peroxide. It is noteworthy in this connection that in electrolytic methods for the determination of lead as lead peroxide it has been found necessary to dry the peroxide at about 150° C., or else the results obtained are inaccurate, and this inaccuracy is supposed to arise from the product being a hydrated peroxide.

PRIOR to 1891 the action of the battery was ascribed solely to the formation of sulphate on both plates during discharge, which sulphate was during charge converted into peroxide of lead on the positive plate, and spongy lead on the negative plate; and no account whatever was taken of any other effects of electrolysis on the acid in the cell. But in this year Mr. ROBERTSON advanced the persulphuric theory which has found such a warm advocate in Mr. BARNETT. This theory was based on the fact that persulphuric acid and its decomposition product, hydrogen peroxide, were found present in the acid of every cell examined, but in those cells which contained sodium sulphate in the acid the characteristic peculiarities of the lead cell were less marked, and at the same time, the amount of the oxidised bodies in the acid was reduced. Cells containing this solution also suffered less on rest. In the following year Messrs. GLADSTONE and HIBBERT brought forward what may be styled the hydrate theory, by which the variations in electromotive force observed on breaking the charging or discharging circuit, the high initial electromotive force, and the sudden fall at the end of discharge with the corresponding rapid recovery, were all accounted for by the variations in the density of the acid *next* the plates which take place during the working of the cell. At the end of charge the acid next to and in the positive plate is very concentrated, and the electromotive force is correspondingly high, while at the end of discharge the rapid weakening of the acid which takes place at both plates produces a rapid lowering, and the diffusion of the acid when the current is stopped accounts for the recovery of the cell. Thus the electromotive force of the cell depends upon the hydrate of sulphuric acid which is next the electrodes at any given moment, and the electromotive force developed is, therefore, a function of the concentration of the acid.

FEW persons nowadays believe in the sulphate theory in its original simple form, so that for practical purposes we may say that there are now only two theories in vogue respecting the working of lead batteries; according to the one, the working of the cell depends on the products of electrolysis formed in the acid, and those products vary somewhat with its concentration. According to the other, the electromotive force of the cell is due to the strength of the acid or the hydrate which is next the plates at any given moment. These rival theories will be found fully set forth in Messrs. GLADSTONE

Digitized by Google

and HIBBERT'S Paper "On the Causes of the Changes of Electromotive Force in Secondary Batteries," and the reply thereto by Dr. H. E. ARMSTRONG and Mr. G. H. ROBERTSON, read before the Institution of Electrical Engineers in May, 1892. Whichever theory be right, there can be no longer any doubt that persulphuric acid *is* formed very frequently, if not always, in the working of secondary batteries, and this is a point about which considerable scepticism was felt when Mr. ROBERTSON published his work. At that time a small anode and high current density were considered necessary for its production, probably because MCLEOD had observed these conditions in his experiments carried out on the electrolysis of sulphuric acid solutions of different strengths in 1886. As our columns show, the formation of persulphuric acid has been noted not only in the case of secondary batteries, but in that of industrial operations involving the electrolysis of sulphuric acid; and though its mere presence does not prove that it is necessary to the working of the process in which it is formed, still it is an endothermic compound which must therefore occasion loss of energy in its formation, and its decomposition product, hydrogen peroxide, cannot fail to be deleterious. It seems highly desirable, therefore, that the conditions which determine the production of persulphuric acid during electrolysis should be carefully studied with a view to its elimination or diminution.

**Sir John Pender.**—Tuesday's *London Gazette* contains a notification that Sir John Pender, G.C.M.G., M.P. for the Wick Burghs, has accepted the Chiltern Hundreds.

**City and Guilds of London Institute.**—Particulars will be found in another column of the sessional course of instruction in engineering and chemistry, &c., for session 1896-97.

**The P.Q. Atlantic Cable System.**—The "Seine" has completed the first repair in this system and proceeded to the locality of the deep water break on the other side of the ocean.

**Dynamo and Transformer Construction.**—A course of lectures to the senior students of the Electrical Standardizing Institution will be given by Mr. James Swinburne, on "Dynamo and Transformer Construction," commencing June 2nd.

**The Pacific Cable Conference.**—Mr. H. W. Mercer, one of the private secretaries to Mr. J. Chamberlain, has been appointed secretary to the conference to be held at the Colonial Office to discuss the scheme for laying a cable *viâ* Canada to Australia.

**The Hopkinson Three-Wire Patent.**—The Judicial Committee of the Privy Council have fixed July 15th as the date for hearing the application for the prolongation of the Hopkinson three-wire patent, No. 3,756 of 1882, now owned by the Westinghouse Company.

**The Toronto Meeting of the British Association.**—The Council of the British Association have, says *Nature*, resolved to nominate Sir John Evans, K.C.B., treasurer of the Royal Society, for the presidency at the meeting which will be held next year in Toronto.

**Hungarian Honours.**—Among the recipients of honours from the Budapest University, on the occasion of the celebration of the Hungarian millenium, were Lord Kelvin, Sir Joseph Lister, Herbert Spencer, M. Berthelot, Prof. Virchow, Prof. H. Sidgwick, and Prof. Max Müller.

**A Double-Distilled Doctor.**—The Vienna correspondent of a daily paper solemnly asserts that among the scientists to receive honorary doctorates from the Budapest University, on the occasion of the Hungarian millenium, were "Lord Kelvin (London), and Sir William Thomson (Glasgow)"

**Obituary.**—We regret to record the death last week of Mr. J. A. Kingdon, whose name will be known to many readers of *The Electrician* in connection with an "inductor" alternator. Mr. Kingdon was a frequent contributor to the technical press, and recently written a work on "Applied Magnetism."

**Cable Interruptions and Repair:—**

| | Date of Interruption | Date of Repair. |
|---|---|---|
| Shanghai—Nagasaki ..... | May 5, 1896 ... | May 7, 1896 |
| Puerto Plata—Martinique..... | Dec. 19, 1895 ... | — |
| Ceara- Maranham ..... | April 28, 1896 ... | — |

**New York-Haiti Cable.**—The manufacture of the New York-Haiti cable has been commenced at the works of the Société Industrielle des Téléphones at Calais. This cable will place Brazil, Dutch Guiana, French Guiana and the French West Indies generally in communication with France, by what is virtually, if not in effect, an all French line.

**Tramway Bills.**—In the House of Lords on Monday last Lord Tweedmouth moved:—"That Standing Order 133A, relating to tramway Bills, be suspended for the remainder of the Session." He explained that the Standing Order was one which prohibited or impeded the consideration of clauses in that House empowering corporations to work their own tramways.

**Royal Institution.**—The Duke of Northumberland, President of the Royal Institution, has appointed the following Vice-Presidents for 1896-97:—Sir Frederick Abel, Lord Kelvin, Mr. George Matthey, F.R.S., Mr. Ludwig Mond, F.R.S., Earl Percy, Mr. Basil Woodd Smith, Sir James Crichton-Brown (treasurer), and Sir Frederick Bramwell (hon. secretary).

**Analyses of British and Foreign Coals.**—In the March number of *Electrical Engineering*, of Chicago, there is an extensive table giving analyses and calorific values of a large number of American and European coals. This table covers some 21 pages, and should form a useful work of reference for engineers interested in the use of coal. We should add that 17 pages of the table are exclusively devoted to United States coals.

**Appointments Vacant.**—The Committee of the City and Guilds of London Institute invite applications for the Professorship of Mechanical Engineering and Applied Mathematics at the Technical College, Finsbury, E.C. Salary £600 per annum. Applications must reach the Hon. Secretary, City and Guilds of London Institute, Gresham College, E.C., by June 8th.——The Governors of the Northern Polytechnic Institute, Holloway, invite applications for the position of Head of the Physics and Electrical Engineering Department. Commencing salary £250 per annum. Further particulars appear in our advertisement columns.

**Progress of Electric Traction in America.**—Commenting on the statistics of European electric traction systems, which were published recently in *l'Industrie Electrique*, our contemporary, the *Electrical Engineer* of New York, remarks that, notwithstanding "the marvellous rapidity with which electric traction was adopted in the United States . . . it has taken practically ten years to convince Europe that the horse could no longer compete for dividends with the trolley." Our contemporary adds the following table of statistics of traction systems in the United States:—

| | Miles. |
|---|---|
| Length of electric track ..... ..... ... | 10.363 |
| Length of horse track ..... ..... ..... | 1,914 |
| Length of cable track ..... | 632 |
| Length of miscellaneous track ..... | 679 |
| Number of electric cars ..... | 24.745 |
| Number of electric roads..... | 976 |

**A Novel Method of Utilising Water Power.**—Particulars of a new method of utilising the power of falling water are given, as follows, in the *Mining and Scientific Press*:—

The essential principal involved is the compression of air by the force of the falling water, and the compressed air used to drive motors at the falls or be transmitted to a distance for the same purpose. From a tank or a standpipe, in which the water stands at the same level as above the dam, the water is permitted to pour down a pipe, around whose base are a number of holes, admitting air from tubes running up to the surface of the water. The air is sucked in and compressed by the water, and the two are automatically separated by gravitation, the air passing into a storage or supply chamber. The incredible statement is made that from 70 to 80 per cent. of the latent energy in the falling water can be rendered available in this manner. This is no more than a turbine yields, but the latter cannot

Digitized by Google

transmit its energy to a distance without the interpolation of dynamos and motors, in which some loss of power occurs. It is said a plant operating on this principal is to be installed at the Dominion Cotton Mills in Magog, near Montreal.

**Royal Society Selected Candidates.**—Amongst the 15 candidates selected for admission into the Royal Society this year we note the name of Prof. Andrew Gray. He was born at Lochgelly, Fifeshire, in 1847, and received his higher education at the University of Glasgow. Prof. Gray was for some time private secretary and experimental assistant to Lord Kelvin. While serving in this capacity Prof. Gray had for a short time as a fellow student Prof. J. Perry, and assisted in the carrying out of the greater part of Lord Kelvin's researches on "The Effects of Stress on Magnetisation." In 1880 Prof. Gray became official assistant to Lord Kelvin, and in 1884, on the foundation of the University College of North Wales at Bangor, he was appointed professor of physics, a post which he still holds. The following are some of the contributions of Prof. Gray to contemporary science:—A well-known book on "Absolute Measurements in Electricity and Magnetism," a Paper communicated in 1883 to the *Philosophical Magazine* on "The Determination in Absolute Units of the Intensity of Powerful Magnetic Fields"; communications on "The Dynamical Theory of Electro-Magnetic Action" and "On the Calculation of the Induction Coefficients of Coils," also made to the same magazine. Prof. Gray is a Fellow of the Society of Edinburgh, and a member of the Physical Society. He is Examiner in Mathematics and Natural Philosophy for Degrees in Arts in the University of Glasgow and in Physics for Degrees in Medicine for the same University.

**Applied Electro-Chemistry.**—Before dealing with the main subject of his third Cantor lecture, Mr. Swinburne referred to the electrolytic recovery of tin from scrap. His own experience had been that it was easy enough to do this in a solution of hot caustic, but *the* difficulty was to find the scrap from which to skin the tin; no one seemed to have any for sale. Coming then to the electrolysis of fused salts Mr. Swinburne remarked that the importance of the process was generally overlooked, it was forgotten how immensely greater the conductivity of fused electrolytes was as compared with that of ordinary ones. The primary batteries, with fused electrolytes as generally described, would not work. Turning to the electrolysis of fused common salt the lecturer pointed out the great complexity of the Leblanc process, in which there were six or eight oxidising and reducing steps to procure the final result Na and Cl. The real difficulty in the electrolysis of NaCl was not the anode or the cathode, most kinds of carbon did fairly well as anodes and any material nearly did as cathode; *the* problem was how to collect the products of electrolysis. Another puzzle was the small amount of sodium obtained. Some suspected a sub-chloride was formed. Examining salt left on the electrode under the microscope it was seen to contain a number of black specks, and on placing it in water gas was given off; this looked as if the sodium were not deposited right on the electrode but in its vicinity, and a lot consequently got carried away. A caustic soda process proposed by Vautin was then described. The principle of this ingenious process is to use fused lead as a cathode to the fused salt, the sodium forming an alloy with the lead which, in the presence of water, yields up the sodium, forming caustic. The lecturer pointed out that in dealing with chlorine by the *wet* electrolytic process, using carbon electrodes, a certain quantity of $CO_2$ was formed and passed off with the chlorine gas into the lime, forming chalk instead of bleach. Allusion was then made to the commercial possibilities of the electrolysis of fused lead chloride, of "fractional" electrolysis of mixtures of fused salts, and to the Hoho process of electrically heating metals under water.

**Third Congress of Chambers of Commerce of the Empire.**—The Council of the London Chamber of Commerce decided, early in 1895, to summon a Third Congress of Chambers of Commerce of the Empire for 1896. Since that time arrangements for the meeting have been continuously in progress, under the charge of the Organising Committee. In its Honorary President the Congress has the influential support of the Secretary of State for the Colonies, who has, by his despatch to the Colonial Governors, and by becoming Honorary President of the Congress, manifested a sincere desire to do everything in his power to promote the success of the gathering. The Council, after conference with Mr. Chamberlain, have selected the week commencing June 8th for the meetings of the Congress. Through the courtesy of the Master Wardens and Court of Assistants of the Worshipful Company of Grocers, the Hall of that Company (Princes'-street, Bank) has been placed at the disposal of the Chamber for the week June 8th-13th, and the business proceedings will open there on Tuesday, June 9th. As far as accommodation permits, members will be afforded an opportunity of being present during the debates. An appeal is made by the Council and the Organising Committee for financial support. Without such support they will be unable to receive and entertain the delegates to, and the distinguished personages who have associated themselves with, the Congress, in a manner either fitting to the character of their guests or creditable to the City of London. The following arrangements have already been made:—Monday, June 8th.—Visit to the East London Trades, Industries and Arts Exhibition (People's Palace). Tuesday, June 9th.—Official Welcome of the Delegates, at 10 a.m., by the Secretary of State for the Colonies in the Hall of the Grocers' Company; Evening Reception by the Right Honourable the Lord Mayor at the Mansion House. Wednesday, June 10th.—Second Meeting of the Congress, 10 a.m. to 4 p.m.; Banquet to Delegates in the King's Hall, Holborn Restaurant, the Right Hon. Joseph Chamberlain, M.P., to preside. Thursday, June 11th.—Third Meeting of the Congress. Friday, June 12th.—Fourth Meeting of the Congress. Saturday, June 13th.—Garden Party by the Right Honourable the Earl of Jersey, G.C.M.G. (late Governor of New South Wales) at Osterley Park, Isleworth. Official Reception, in the evening, at the Imperial Institute, by the Right Hon. Joseph Chamberlain, M.P., and Mrs. Chamberlain, to have the honour of meeting His Royal Highness the Prince of Wales.

**Contemporary Electrical Science.**—An important question connected with the forbidding subject of electric execution is discussed by G. Darin in *L'Eclairage Electrique*. It is as to whether life can be pronounced extinct when no organic lesions are discovered which under ordinary circumstances would be sufficient to cause death. According to the late M. Brown-Séquard and M. d'Arsonval, the administration of alternate currents of high frequency causes stoppage of respiration and syncope. But death may be only apparent, and the victim may be restored by artificial respiration. Only in two cases out of 26 executions do the official reports state that intercranial effusions of blood were found which would ensure death. But, nevertheless, the physicians always declared death to be absolute. The author believes that the only satisfactory test for death is an unsuccessful attempt at restoration. In the same number A. Righi writes further on the globular discharge which he has succeeded in imitating by means of a large condenser discharging through a very high resistance. In a rarefied gas discharges may be obtained lasting several seconds. The globes start from the positive electrode, increase in size, and move slowly towards the cathode, but never reach it. They can be easily followed with the eye or photographed.——M. Ascoli, in the *Nuovo Cimento* describes some interesting magnetic experiments giving quantitatively the amount of disturbance caused by a magnetic substance when placed in a uniform magnetic field. He finds that there is perfect continuity in the components of the external and internal fields, and that the outermost skin of the magnetic substance exerts no superficial protective action upon the inner layers.——A Paper on X-luminescence, by which name the fluorescence produced by Röntgen rays is known in Germany, is contributed to the *Zeitschrift für Electrochemie* by W. Arnold. He finds that Lenard rays and X-rays may have very different effects. Salts of manganese, lithium, cadmium and strontium, which are so very sensitive to Lenard rays, are quite indifferent to X-rays. So is $CaSO_4$, with an admixture of $MnSO_4$, Lenard's chief fluorescent substance. The best substance for X-luminescence is scheelite, a tungstate of calcium. This may be obtained artificially by making a "solid solution" of copper tungstate in calcium tungstate.

## THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS.*

BY F. C. RAPHAEL.

(*Continued from page 10.*)

*The Weston Circuit Tester.*—This is an instrument designed to indicate the condition of the mains of a two-wire network on the principle just described. It is actually a voltmeter of about 30,000 ohms resistance, giving readings to both sides of the scale; the scale is equally divided throughout its range. The positive and negative mains are connected to the two binding-screws marked + and − (Fig. 1), and there is a binding screw not seen on the drawing to connect to earth. This

FIG. 1.

latter is one terminal of the voltmeter. On depressing the left-hand key the other voltmeter terminal is connected to the + main; on depressing the right-hand key this terminal is connected to the − main. The connections are shown diagrammatically in Fig. 2. There is, of course, a contrivance to prevent both keys from being depressed at the same time.

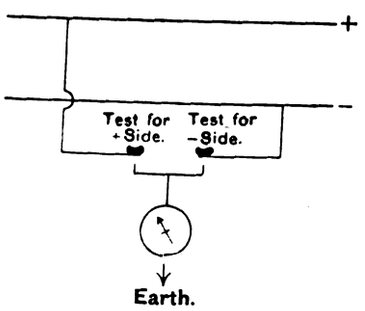

FIG. 2.

The two readings are relatively proportional to the fault resistances of the two mains. The actual value of the fault resistances can be calculated by the formula (10) already given, viz.:

$$f_1 = \frac{g\{V-(d_1-d_2)\}}{-d_2},$$

$$f_2 = \frac{g\{V-(d_1-d_2)\}}{d_1}.$$

$d_1$ and $d_2$ being always to opposite sides of the scale, the two deflections must be added to give $d_1 - d_2$.

Owing to the high resistance of the instrument this calculation of the fault resistances will not be accurate except for networks of high insulation resistance—of a thousand ohms or so. In networks of lower insulation resistance the expression $d_1 - d_2$ will be nearly equal to V, so that $V-(d_1-d_2)$ will only be obtained to a small degree of accuracy. The two readings are, however, relatively proportional to the fault resistances of the two mains, whatever the resistance of the voltmeter. The instrument is on the d'Arsonval principle, similar to other instruments of the Weston manufacture. The resistance of the moving coil itself is only a few ohms, the high resistance being simply a dead resistance placed in series with it. If this resistance were replaced by two lower resistances, one in series with, and the other shunting the moving coil, so as to make the resistance between the terminals more nearly equal to the resistance to be measured, the instrument would be more useful. It could then be used with advantage on networks of moderately high insulation resistance—say of 50 or 100 ohms and upwards—and on three-wire as well as on two-wire networks. The equally-divided scale is a very good feature.

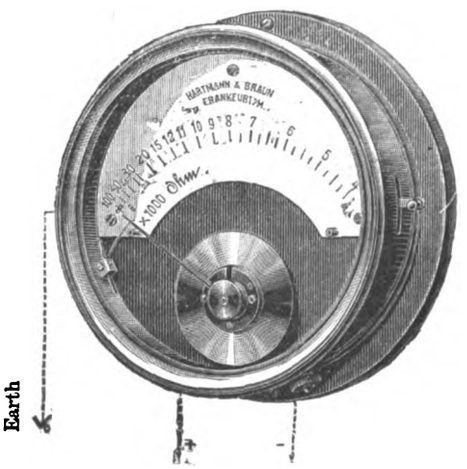

FIG. 3.—Hartmann and Braun's Leakage Indicator. One-fourth full size.

*Hartmann and Braun's Leakage Indicator.*—This is also intended for use on a two-wire network of high-insulation resistance. Fig. 3 is a drawing of the instrument and Fig. 4 is a diagram of its connections. The lever switch on the

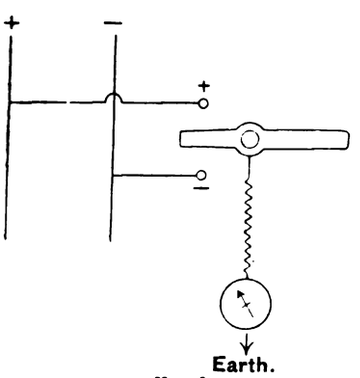

FIG. 4.

instrument is first put in the position + (Fig. 4) and then to −. If a deflection is obtained in one of these positions only, the resistance shown will be the fault-resistance of the opposite main. That is to say, if when the lever key is on + there is a reading 5 on the scale, and when the lever key is at − the needle remains at the mark $\infty$, the fault resistance of the negative main is 5,000 ohms, and that of the negative main is high in comparison. If deflections are obtained in both positions of the switch, the fault resistances of the mains are not equal to the readings, but must be calculated from the following formulæ:—

$$\left.\begin{aligned} f_1 &= d_2 - \frac{d_2+g}{d_1+g}\cdot g \\ f_2 &= d_1 - \frac{d_1+g}{d_2+g}\cdot g \end{aligned}\right\}, \quad \ldots\ldots \quad (15)$$

$d_1$ and $d_2$ being the readings, and $g$ being the resistance of the instrument.

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

The "leakage indicator" is made for a variety of pressures from 65 volts upwards. The 110-volt instruments have a resistance of about 1,000 ohms, and scale readings from 100,000 to 4,000 ohms.

It is, therefore, only in special cases that the low-pressure type of this instrument can be used.

*Method 2.**—A voltmeter or milliampere-meter is used whose resistance is high compared with the insulation resistance of the mains, and which gives readings to both sides of zero; or any galvanometer of high resistance whose readings are proportional to the currents through it. (The instrument need not be direct-reading.) This is connected between one main of the network and earth (Fig. 5A), and a reading $d_1$ is obtained. Then the instrument is shunted by an adjustable resistance $s$ (Fig. 5B), which is adjusted until the new reading $d_2$ is half of $d_1$. Then *$s$ will be equal to the insulation resistance of the network.*

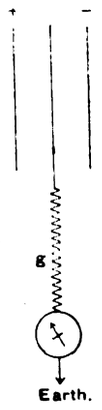

FIG. 5A.

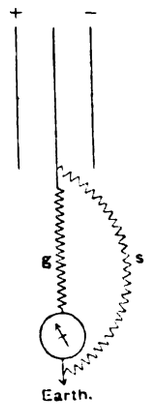

FIG. 5B.

If $s$ cannot conveniently be made small enough, $d_2$ can be made $= \frac{2}{3}\, d_1$; then $F = \frac{s}{2}$.

Or $d_2 = \frac{3}{4}\, d_1$; then $F = \frac{s}{3}$, &c., &c.

The equation connecting $d_1$, $d_2$, $s$, F and $g$ is

$$\frac{1}{F} = \frac{d_2}{(d_1 - d_2)\, s} - \frac{1}{g}. \quad . \quad . \quad . \quad . \quad (16)$$

It is therefore convenient to make $g$ so large that $\frac{1}{g}$ can be neglected, and then simply

$$F = \frac{d_1 - d_2}{d_2}\, s, \quad . \quad . \quad . \quad . \quad . \quad (17)$$

which gives the rule above.

In three or five-wire networks of moderately high insulation resistance—say about 100 ohms—this method is very practical. Then the instrument should be connected between the middle wire and earth, and the resistance $s$, with which it is shunted to obtain the second deflection, can be an ordinary resistance-box if the test be quickly made. A resistance coil must be put in series with the instrument, if necessary, to fulfil the condition that the instrument resistance is great compared with the insulation resistance to be measured.

In the diagram, Fig. 5B, such a resistance has been inserted. The position of the shunt coil in the diagram must be noted. It is not in this case connected to the galvanometer terminals, but shunts the series coil and galvanometer together.

The actual error in the measured insulation resistance, introduced by neglecting the effect of the galvanometer resistance, can be seen by applying equation (16); but it should be remembered that, though the error in the actual calculated insulation resistance may be appreciable, the relative error in comparing the tests of two different days is small.

If the fault resistances of the positive and negative sides of a three-wire network are nearly equal (or in a five-wire network if the equation (14) be nearly satisfied), only a small reading will be obtained when the instrument is connected to the middle wire. The readings can then be obtained from either of the other mains, but in that case special resistance coils designed to stand larger currents must be used for $s$, as the coils of an ordinary resistance box would be damaged by the larger currents. Such coils capable of standing larger currents must also be used when this method is employed on two-wire networks, or on three and five-wire networks of lower insulation resistance.

When the test indicates a drop in the insulation resistance of the network, it is easy to see whether the fault has occurred on the positive, negative or neutral main, if the testing has been done on the middle wire. If the current flowing through the instrument *from* the network *to* earth be considered as giving a + deflection, a fault in the positive wire will diminish the deflection if +, and augment it if −; a fault in the negative wire will have the opposite effect. A fault in the middle wire will only slightly diminish the deflection, though the value of $s$ will be diminished.

FIG. 6A.

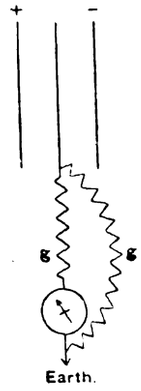

FIG. 6B.

So as to order a milliampere-meter or voltmeter for this test, the value of $d_1$ may be predetermined if the fault resistances of the several mains be known. If a milliampere meter be used the current can be calculated from one of the equations (11) to (13). The $d_2$ in these equations gives the current when the instrument is connected between the middle wire and earth, and is not shunted. If a voltmeter be used, V must be substituted for $\frac{V}{g}$ outside the bracket in these equations. If $g$ is going to be made high, so as to have a practically direct-reading method, $\frac{1}{g}$ can be neglected in the fractions inside the brackets.

*Method 3.*—This is a modification of the preceding method. An ammeter or voltmeter is connected between one of the mains and earth as in Method 2, and the reading $d_1$ is taken (Fig. 6A). Then the instrument is shunted by a resistance exactly equal to its own resistance, and the reading $d_2$ is noted (Fig. 6B). The insulation of the network is calculated from the formula

$$F = \frac{d_1 - d_2}{2d_2 - d_1}\, g \quad . \quad . \quad . \quad . \quad . \quad . \quad (18)$$

This method is suitable for networks with high or low insulation. The formula, though simple, is absolutely correct, and not an approximation, and applies whether a voltmeter or ammeter has been employed, or a galvanometer (which need not be direct-reading, but must give deflections proportional to the current through it).

The instrument to choose for this test should be one of resistance about equal to the insulation resistance of the network, or, if one of lower resistance be employed, a resistance coil should be added in series with it. Then $d_2$ will be about two-thirds of $d_1$.

An ammeter or milliampere-meter will be found most convenient for networks which have not very high insulation resistances. To ascertain the range to order for the instrument the value of $d_1$ may be calculated from one of the equations (11) to (13). The $d_2$ in these equations will give the current if the ammeter is to be connected between the middle

* This method is due to Dr. O. Frohlich, of Berlin. *E. T. Z.*, January 27, 1893, and *The Electrician*, February 10, 1893.

Digitized by Google

wire and earth, as in Fig. 6A. If a voltmeter be used instead of an ammeter, V must be substituted for $\frac{V}{g}$ outside the bracket in these equations.

A hot-wire voltmeter will not give accurate results if used for testing by this method or Method 2, for reasons already explained.

If the instrument is connected to the middle wire, on a fault occurring it is possible to see at once on which main it is, as shown in the consideration of Method 2. If the fault has occurred on the middle wire the absolute values of $d_1$ and $d_2$ will not alter so much as when a like fault occurs on one of the other mains.

The tests for this method may be made on any of the mains of the network, though for the sake of convenience the use of the middle wire is preferable when possible.

In cases where the fault resistances of the positive and negative sides of the network nearly balance one another, it is still possible, by a simple expedient, to obtain the readings from the middle wire. A resistance of known value is connected, as an artificial fault, between one of the other mains and earth (Fig. 7), and so destroys the balance.

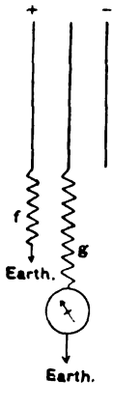

FIG. 7A.

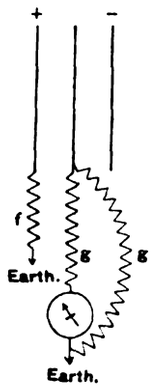

FIG. 7B

Then the insulation resistance F′ is calculated from the formula (18), and the real fault resistance of the network is obtained by the formula

$$\frac{1}{F} = \frac{1}{F'} - \frac{1}{f} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (19)$$

where $f$ is the resistance of the artificial fault.

*(To be continued.)*

## ELECTRIC TRANSMISSION OF POWER FOR A PAPER MILL AT ROMAGNANO.

An interesting application of electric polyphase transmission to the driving of paper-making machinery has been carried out by the Vonwiller Company to supply power to its large paper mill in Romagnano-Sesia (Italy), the power being derived from a waterfall 5 kilometres distant. The plant, the capacity of which amounts to 810 H.P., was installed by the direction of Messrs. Brown, Boveri and Co., of Baden (Switzerland), and has now been in successful operation for over a year. A general test of its commercial working was executed by Mr. A. Nirrola, who has recently published a complete description of the whole installation giving the results obtained in testing. We quote from his Paper the data of most interest.

The power station is driven by a waterfall on the river Sesia, near Giarola, having a capacity of 8 cubic metres of water per second, and a fall of 10·5 metres. Three vertical Bell turbines of 270 H.P. each have been installed, and drive at 180 revolutions per minute three 195-kilowatt Brown two-phase alternators direct-coupled to the turbines.

The alternators (Fig. 1) consist of a fixed external ring armature and an internal revolving inductor, with radial projecting poles. No winding is visible on the exposed surface of the armature, the active conductors being all embedded in longitudinal holes just near the internal surface. The formation of eddy currents in pole-pieces is thus avoided, and these may be constructed of massive metal. The inductor, of steel casting, is umbrella-shaped, and is wound with 28 poles, half of which are cast with the frame, the other half being secured by bolts; the latter only carry the winding coils, room for which is provided by concavities contrived in the side surfaces of the former ones, such disposition, which constitutes the subject of a patent by Mr. Brown, having the advantage of permitting the employment of cylindrical coils without loss of space. Another peculiarity of the machine is the situation of both bearings supporting the main shaft below to the inductor body, the arrangement adopted being intended to simplify the construction and to facilitate repairs and taking out of the

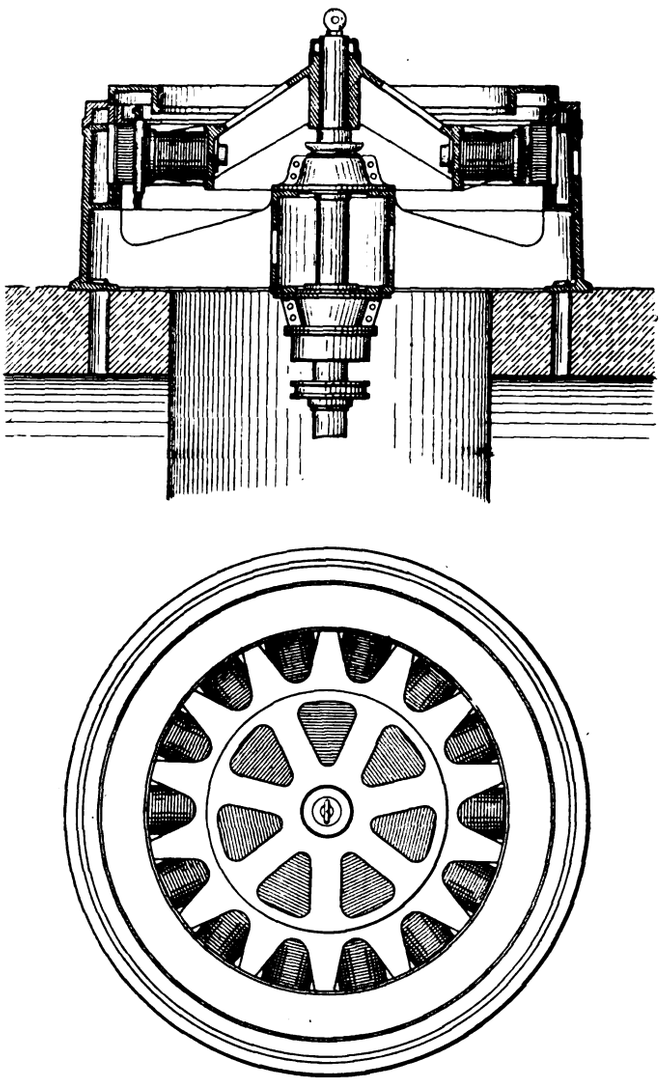

FIG. 1.—Vertical Section and Plan of 195-kilowatt Two-Phase Brown Alternator.

working parts. The exciters of the alternators are two Manchester dynamos, one of which is intended as a reserve; these are fixed in vertical position to the wall, and are driven, at 500 revolutions, by two direct-coupled 25 H.P. turbines.

A *two-phase* system of transmission, with 83 alternations per second, and direct generation at 3,600 volts from the dynamos, has been adopted in this installation. From each generator start four copper conductors, which, crossing the machinery hall underneath the floor, and concealed in the wall, carry the currents to a switchboard of simple construction. The connections of this are shown in the annexed illustration (Fig. 2), and permit the interchange of any generator, and the hand regulation of pressure. No difficulty is experienced in the parallel coupling of the alternators. This operation is accomplished by phase indicating lamps, fed by three 200-watt trans-

Digitized by Google

formers, to which the voltmeters also are connected; a fourth transformer, shunted from the main bars, is inserted in series with the lamp circuit, so as to get the synchronism indicated by the *incandescence* instead of, as usual, by the *obscurity* of the filaments, with an obvious advantage.

An aerial line, 5 kilometres (3 miles) long, and consisting of four independent wires of 8mm. diameter, transmits the current to the paper works, where it is transformed down to 230 volts, for the supply of motors, by seven 90 kilowatt two-phase transformers; and by two of 15 kilowatt for lighting purposes. The

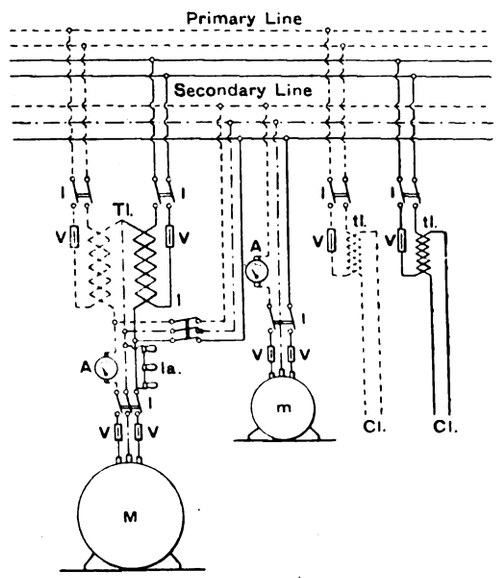

FIG. 3.—Diagram of Receiving Station Connections.

switchboard connections for these are shown in Fig. 3. Six of the 90-kilowatt transformers run each a 120 H.P. motor, driving the paper-making machinery; they are independent of one another, but may be all cross-connected by a collecting network, so as to distribute if necessary the power from the more loaded to the less-loaded ones. The seventh transformer is not connected to any particular motor, but directly to the network, and is intended thus to act as a reserve for substituting for any disabled one. The network extends through the whole premises of the factory, and supplies power, not only to the six main motors, as mentioned, but also to a certain number of small motors, distributed throughout, and ranging from 3 H.P. to 15 H.P. each. It consists of only three wires of 8mm. diameter, the two circuits having a common return conductor, which, for the sake of simplicity is kept of the same size as the others.

The method adopted to solve the difficulties connected with the construction of the motors is worthy of notice. The conditions to be fulfilled in the working of these were in effect by no means easy:—A start under full load with no more than the normal current, no commutators nor sliding contacts. The inductor part of these motors is external and fixed, the rotating armature internal, as usual; to obtain full torque at starting, while preventing an extraordinary flow of current from the line, a resistance is inserted in the armature circuits, to be switched out when full speed is attained. This resistance is contained in the rotating part of the motor (Fig. 4), and to enable its disconnection while running, a screw-acting device is provided; the friction of the hand pressed on the surface of a small drum mounted on the axle causes the screw to advance and press a gun-metal cone against its rest, thus short-circuiting the armature. Successful results have been secured by this arrangement.

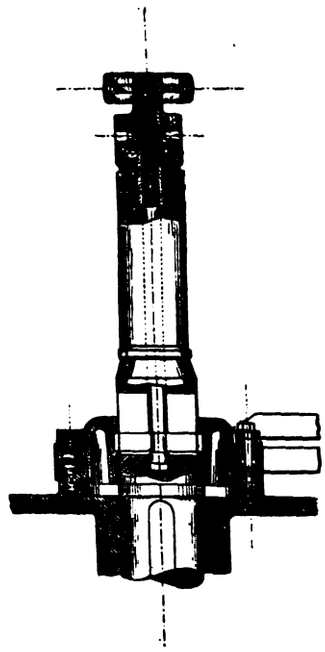

FIG. 4.—Screw-acting Device for Cutting out and Starting the Resistance in the Armature Circuit of Induction Motors.

The 120 H.P. motors experience a variation of 7 per cent. in speed when rising from no load to a 10 per cent. overload, the apparent power absorbed in internal losses being 26 volt-amperes at no load, 88 at 100 H.P. load, at 120 volt-amperes at 136 H.P. load. The tests of the plant show the efficiency of the whole electrical transmission equal to 80 per cent., so that of 810 H.P. available on the turbines at the power house 648 are delivered to the motors at Romagnano.

## EARTHING DEVICE FOR THE PROTECTION OF TELEPHONE CIRCUITS FROM ELECTRIC TRAMWAYS.

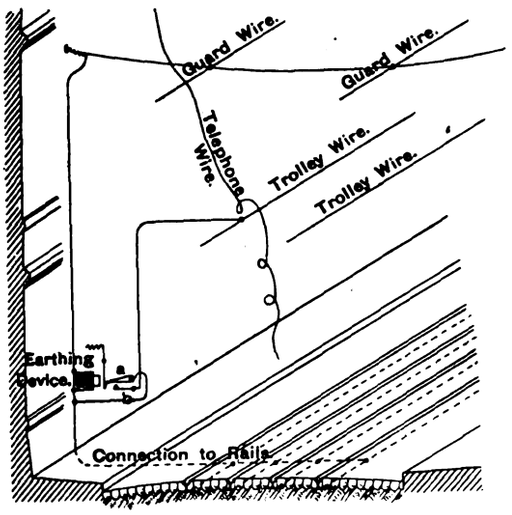
In our issue of April 17, 1896, p. 819, we published some details of safety devices for telephonic circuits devised by the Allgemeine Elektricitäts Gesellschaft in connection with electric tramways, and also details of some experiments made with these devices under various conditions. In the opinion of the German Post Office authorities, however, there are cases where the application of this plan would cause difficulties, and another arrangement

Digitized by Google

seemed therefore desirable. In Chemnitz, a little while ago, a telephone wire broke, fell on the trolley wire and killed some horses. Herr R. Ulbricht has now made some experiments with an earthing device, which he has invented, and which he describes in the issue of the *Elektrotechnische Zeitschrift* for May 7th. He has repeatedly observed that when the telephone wire falls on an earthed guard wire, and then on the trolley wire, it does not fuse at the latter point of contact, but always at the point of contact with the guard wire. The dead piece of wire then hangs from the trolley wire down into the street, and as the earth detector at the generating station does not any longer show an earth, the automatic cut-out is closed again to the danger of traffic.

This observation induced Herr Ulbricht to design a new arrangement, which has, as tests have proved, given satisfactory results. The arrangement is based on the idea of creating a permanent earth, by means of a momentary one, which can only be removed by an authorised official. The arrangement is shown in the accompanying figure. The shortest contact between telephone wire, trolley wire and guard wire causes a permanent contact at *a b*. The automatic cut-out will then act with certainty, and the short-circuit indicator will show a permanent disturbance until the earthing device near the point of disturbance is reset. As we are dealing here with a great public danger a short stoppage of the working of the line cannot be considered a serious disadvantage.

On February 8th last some experiments were made with this new arrangement on the electric tramway at Zwickau, Saxony. The earthing device, although it was only put roughly together, acted properly. At each fall of the wire the needle of a voltmeter



connected between trolley wire and earth fell at once back to zero. The protection afforded was complete, and even an 8-ohm fuse intended for a maximum current of $\frac{1}{3}$ ampere, when put in circuit with the falling wire, remained intact. At the final experiment the guard wire, which had been weakened considerably by the different contacts burned through, but the short time of contact was enough to cause the earthing apparatus to act.

This device has the advantage of enabling thinner guard wires to be employed, as they have only to take a momentary current; a greater distance between guard wire and the trolley wire is also permissible. Again, an earth produced in this way will cause the automatic cut-out to act with certainty. The device can be easily examined and tested daily, but of course care must be taken to prevent contact at *a* and *b*.

The electric tramway at Zwickau has now been fitted with this apparatus, and on an artificial break of the telephone wire being made the arrangement acted with certainty.

## ITALIAN RÖNTGENIANA.

The Röntgen fever has invaded Italy, and our Italian colleagues are working as hard as any to unravel the mysteries of the new light. There are Papers in the *Nuovo Cimento*, in full or in abstract, by Battelli, Garbasso, Vicentini, Roiti, Righi, Salvioni, Faé, and Villari, some of which are of the greatest importance. Battelli tries to find the point of origin of the X-rays by the method of the inverse square of the distance, and also by a method which may be described as that of triangulation: letting the rays pass through two holes and impinge on a sensitive plate at some distance, and constructing the paths of the rays by joining the holes with their "traces." He finds that the rays behave as if they started from the surface impinged upon by the cathode rays. Also that Crookes tubes emit X-rays for some time after discharge has ceased. The same author, in conjunction with Garbasso, claims priority for Winkelmann and Straubel's method of shortening the necessary exposure for radiography by placing a fluorescent screen behind the plate. The same object may be achieved by placing strongly fluorescent substances inside the Crookes tube. Vicentini and Pacher, who were among the first to introduce the rays into Italy, claim to have reflected them by means of a large parabolic brass mirror, but irregularly. Prof. Righi describes a way of obtaining images independent of photography. The Crookes tube is placed above a metallic plate. The cathode and the plate are both connected with one pole of a charged condenser. Above the metal plate is mounted a discharged ebonite plate, and between this and the tube is placed a sheet of black cardboard coated with aluminium foil connected to the anode and to earth. The object to be radiographed is placed on the cardboard, and after "exposure" the ebonite is sprinkled with a mixture of sulphur and red lead, or talc and manganese dioxide. The picture comes out clearly owing to the different electrifications of the powders and the exposed and unexposed ebonite. Prof. Salvioni describes some radiographs obtained by him, in which the cartilages of the hand were more opaque than the more spongy portions of the bones, and also a radiagraph of a frog showing the lungs, the heart, and the spleen. The conditions under which the radiographs were obtained are not, however, specified. Prof. Salvioni's much talked of "cryptoscope" consists of a small fluorescent screen mounted at one end of a tube, viewed through a lens at the other end. Both he and Faé succeeded in narrowing the area of origin of the rays by deflecting the cathode rays into a constricted portion of the tube by means of a magnet, or by touching the wall with a metallic point connected to the cathode and to earth. E. Villari claims to have reflected the rays by means of a plate of zinc, in accordance with the ordinary laws of reflection. No other substance showed this phenomenon.

## RÖNTGEN RAYS NOT PRESENT IN SUNLIGHT.*

BY M. CAREY LEA.

If Prof. Röntgen's views as to the nature of the X-rays are correct, it would seem that they ought to be found amongst the many forms of radiant energy received from the sun, and various observers have thought that they so found them. Some experiments, the most important of which will be here briefly stated, do not seem to support this opinion.

1. A very sensitive dry plate (S. 27) was placed between the leaves of a book, so that 100 leaves and the red paper cover should be between the sensitive film and the sunlight. The book was then packed in a box frame to exclude all light from the sides. A large and thick lead star was then fastened on the outside of the book, and the arrangement was exposed to exceptionally bright sunshine from 11 a.m. to sunset, March 7th. The plate when put into a developing bath behaved as if unexposed. A prolonged development did not bring out a trace of an image of the lead star. It will be remembered that Prof. Röntgen found that the X-rays penetrated easily through a book of 1,000 printed pages. Indeed, G. Moreau has recently stated that in his hands the X-rays had penetrated through "several metres" of cardboard. So that the above experiment seems to be very significant.

2. A piece of sheet aluminium 1·2mm. thick was accurately fitted into a frame. A very sensitive plate was placed behind it, and a lead star in front. With three hours' exposure not a trace of an image could be obtained. This experiment was varied by substituting thin aluminium foil for the plate, also by using bromide paper as the sensitive surface. No images in any case were obtained.

3. The sun's rays or some portion of its radiation passes readily through wood if the latter is not too thick. Thus, through a piece of white pine $\frac{3}{16}$ths of an inch thick, images that could readily be developed were obtained by three minutes exposure to afternoon sunlight. With half an hour's exposure the images were brilliant. A panel about 12in. square was removed from an inside shutter and replaced with a piece of white pine $\frac{1}{4}$in. thick. When the room was thoroughly darkened, reddish light could be seen to pass through the board. So that wood of this thickness is plainly translucent to the sight.

The sun's light may be examined for X-rays also by fluorescence.

4. The panel just described was replaced by one of stout book board. With the sun shining on this book board directly and not through glass, paper marked with a saturated solution of barium platino-cyanide exhibited no indications of fluorescence when placed behind the board.

5. Three thicknesses of Bristol board were pasted together, a circle was cut out, to one side of which barium platino-cyanide was applied. The circle was then placed in a pasteboard tube (an arrangement, I believe, proposed by Prof Magie). When the sun

* From the *American Journal of Science*, May, 1896

Digitized by Google

was looked at through this tube, the barium salt exhibited fluorescence. But the interposition between the card and the sun of very thin aluminium foil sufficed to cut off the fluorescence.

These concurrent results seem to indicate the absence of X-rays from sunlight.

M. Charles Henry quotes an opinion of H. Poincaré that all bodies whose phosphorescence is sufficiently intense emit, in addition to luminous rays, the X-rays of Röntgen, whatever may be the cause of their fluorescence. Henry quotes confirmatory experiments of his own made with zinc sulphide. It seemed worth while to ascertain if this principle is of general application. A dilute solution of uranin was exposed to sunlight, using a large surface of solution so as to get the best effect. A short distance over the surface was placed a sensitive film protected by aluminium foil $\frac{1}{10}$th of a millimetre in thickness, and with a lead star interposed. Two hours' exposure gave no result. The experiment was repeated with acid solution of quinine, with which five hours' exposure gave no result.

I have also examined the Welsbach light for X-rays. This light is usually burned under a chimney which increases the brightness but interposes glass between the source of light and the sensitive film. Even without a chimney the light is bright. The experiment was therefore made both ways. No X-rays could be detected. Nothing capable passing through aluminium foil $\frac{1}{10}$th of a millimetre in thickness by five hours' exposure to the uncovered flame.

## EXPERIMENTAL TESTS ON THE INFLUENCE OF THE SHAPE OF THE APPLIED POTENTIAL DIFFERENCE WAVE ON THE IRON LOSSES OF TRANSFORMERS.*

BY STANLEY BEETON, C. PERCY TAYLOR AND J. MARK BARR.

*Introductory.*

At the conclusion of some articles on "Wave-Form Synthesis," which were published in June, 1895,† we mentioned that we were then engaged in testing the iron losses in transformers with the aid of the method we had devised for easily altering the shape of the applied potential difference wave. This question of iron losses has naturally been regarded as one of considerable importance by electrical engineers, since the success of every system of alternate-current supply depends to a great extent on the all-day efficiency of transformers. Hence, we have thought that an account of some fairly complete experiments on this subject might be worthy of the consideration of this Institution. These experiments were carried out at the Central Technical College during May, June and July, 1895.

* Paper read before the Institution of Electrical Engineers.

† *The Electrician*, June 21 and 28, 1895, Vol. XXXV., pp. 257 and 286.

*Work of Previous Investigators.*

Up to August, 1895, when our investigations were completed, the most important contributions to the study of the effect of the shape of the alternating wave on the amount of iron loss in a transformer were the experimental tests of Dr. Fleming* and Mr. Steinmetz,† while the theoretical side of the question had been studied by Mr. Evershed ‡ in 1891, and again more recently by Mr. Feldmann. §

Mr. Steinmetz carried out some tests in America in 1891, with a view to finding "whether there was any difference in the "action of transformers" when worked off alternators of the iron-clad and smooth-core types. An average difference of 9 per cent. in favour of the distorted iron-clad wave was observed; but it should be noticed that in these experiments the power lost in hysteresis was alone considered, whereas the total loss in the iron must decide the question as to which of the two machines it would be better to employ. To make Mr. Steinmetz's test, then, of any real practical value it becomes necessary to assume that the power wasted in eddy-currents does not vary with the form of the E.M.F. wave. And although we now think that this assumption is justifiable (as will be shown later), we do not consider that there was sufficient experimental evidence at that time to entitle Mr. Steinmetz to make this assumption. (It is possible that Mr. Steinmetz may have meant total iron loss when he spoke of hysteresis, but we cannot form any definite opinion on the point from the data given in his letter.)

Dr. Fleming, who found "differences of 10 per cent. and 15 per cent. in the iron core losses," observed that "the iron core loss in any transformer was greatest on that alternator the E.M.F. curve of which most closely approximated to a sine curve." For his tests Dr. Fleming employed several different types of alternators, and this necessarily limited the number of types of E.M.F. waves at his disposal. We think it was this limitation that led Dr. Fleming to the result stated above, for our tests certainly point to a conclusion which differs very materially from this. ||

In a series of articles on transformers in *The Electrician* in 1891, Mr. Evershed dealt pretty fully with the question of the applied P.D. waves and the corresponding iron losses in transformers, chiefly, though, from a theoretical standpoint. He sums up this part of his subject by saying; "The broad lesson to be learnt from the diagrams is, that in studying iron losses in the cores of the transformers we may neglect the slight differences due to widely differing E.M.F. waves." Mr. Evershed has given, in vindication of this statement, three waves (viz., the sine, the rectangular, and the zigzag), which, though they differ considerably

Digitized by Google

in *shape*, do not, for the same effective value, vary much in *area*. This, as we shall show later, is an essential point. It is not, therefore, very surprising that Mr. Evershed did not discover a large variation in the iron loss when considering these wave shapes.

We come now to one of the most recent contributions to this question, namely, that of Mr. C. P. Feldmann. This consists of an entirely theoretical treatment of the subject of this Paper. One or two serious errors have been pointed out by Mr. Hay,* and by one of the authors† of the present communication, in Mr. Feldmann's reasoning. But quite apart from these mistakes we do not think that the principle and methods of this Paper, in which unnecessary complications are introduced, could ever be made of great practical value.‡

## Description of Apparatus.

The method employed in our transformer tests was that of obtaining the complete curves of P.D. and current by means of an electrometer and Joubert contact-maker. This method, while being simple and accurate, is absolutely complete; any results required can be calculated from the two curves taken. The P.D. was kept constant by means of an Ayrton and Mather electrostatic voltmeter; thus we used only electrostatic instruments which required no sort of correction such as is necessary when wattmeters and dynamometers are employed. The method we employed for varying the shape of the P.D. wave impressed on the transformer was, as already stated, the one described in *The Electrician* for June 28, 1895. It consisted in throwing into the circuit, during similar parts of each half-wave, a resistance or capacity by means of an apparatus which we have called the "injector." It is indicated in the accompanying diagram (Fig. 1), which also shows the details of the remainder of the apparatus used by us in testing the iron losses in the transformer.

*The "Injector."*—The arrangement which we have previously called the "injector," is shown diagrammatically at J. It consisted of two brushes, $b_1$, $b_2$, bearing on a commutator keyed to the shaft of the alternator. To these brushes was connected a resistance or capacity, as the case might be. We used a Ferranti alternator giving eight complete periods per revolution, and, in order that we could throw into the circuit any desired resistance or capacity during certain similar parts of *each half-wave*, the commutator was made with 16 segments. These segments—completely insulated from the machine and from one another—had no connections brought to them whatever; they were merely used to periodically short-circuit the two brushes $b_1$, $b_2$. The position of the brush $b_2$ determined the *epoch*, or the instant at which the resistance or capacity was thrown into the circuit, while the distance between $b_1$ and $b_2$ determined the *interval*, or the duration of the effect for any given speed of the alternator. To the other end of the alternator shaft was fixed the usual form of Joubert rotating contact-maker. The movable brush C, and fixed graduated scale, used for taking the wave-forms, were also employed by us to fix the positions of the "injector" brushes in the following manner:—

*Method of Setting the Injector Brushes.*—The normal P.D. wave was first obtained in the ordinary manner, and by this means we really calibrated the fixed scale of the contact-maker; that is to say, we found positions of the brush C corresponding with certain points in the wave of P.D., thus imparting a definite meaning to each point in the scale. Having decided over which part of the normal P.D. wave the injection was to take place, we found the points corresponding with this interval on the fixed scale of the contact-maker. Let these points be $a$ and $d$. The brush C was fixed with the pointer at $a$, and the alternator shaft turned until the metal web of the contact disc came under the brush (this is the position indicated in Fig. 1), and the trailing injector brush $b_2$ was then adjusted till it was about to leave one of the segments. We next moved on the brush C to the point $d$, and turned the shaft of the dynamo until contact between the brush and the metal web was again restored. With the armature in this position the brush $b_1$ was set so that it was just coming on to the next segment behind the one which $b_2$ had been adjusted to leave. It is evident, therefore, that during the interval in which the armature moves from the position $a$ to the position $d$, the resistance or capacity inserted between $b_1$ and $b_2$ would be in the circuit, and that during the remainder of the half-wave it would be short-circuited.

*Transformer Details.*—Our tests were carried out on a Mordey transformer designed for an output of 3 kilowatts. The transformer was wound with three coils, two consisting each of 12 turns, and intended to be used with a pressure of 50 volts, while the third, or fine-wire, coil was wound for a pressure of 2,000 volts. This latter and one of the former were left on open circuit throughout these experiments, and the other coil was used by us as the magnetising coil, taking about 3 amperes at a frequency of 100 ∿. Hence, as the resistance of this coil was only 0·016 ohm, the drop in pressure due to it was negligible.

*Electrometer Connections.*—The instrument used for taking our waves was an Ayrton and Mather quarter-cylinder reflecting electrometer, connected up in series with the Joubert contact-maker as shown in Fig. 1. In parallel with the electrometer we had a small condenser, which was short-circuited by the key K after every reading. A number of water cells (connected with the instrument as shown in Fig. 1) were used to maintain a permanent P.D. between the opposite pairs of quarter-cylinders, and the P.D. to be measured was set up between the needle and the case. This method, as explained in our above-mentioned article, has the advantage of making the deflection directly proportional to the P.D. to be measured, even when the auxiliary P.D. required in the heterostatic use of an electrometer is quite small. The only readings used in working out the tests were those taken with the electrometer; for this instrument was also employed to measure the P.D. between the ends of a non-inductive resistance R, placed in series with the transformer, and so to indirectly measure the current flowing through the latter. The electrometer was calibrated before—and, in almost all cases, after—every test with a set of 70 standard Clark cells. In order to facilitate taking the instantaneous values of both P.D. and current in quick succession, two change-over switches were used at A and B. A consisted of a solid block of paraffin wax, in which were cut two long slots and two rows of small holes, all of which were filled with mercury. The electrometer and

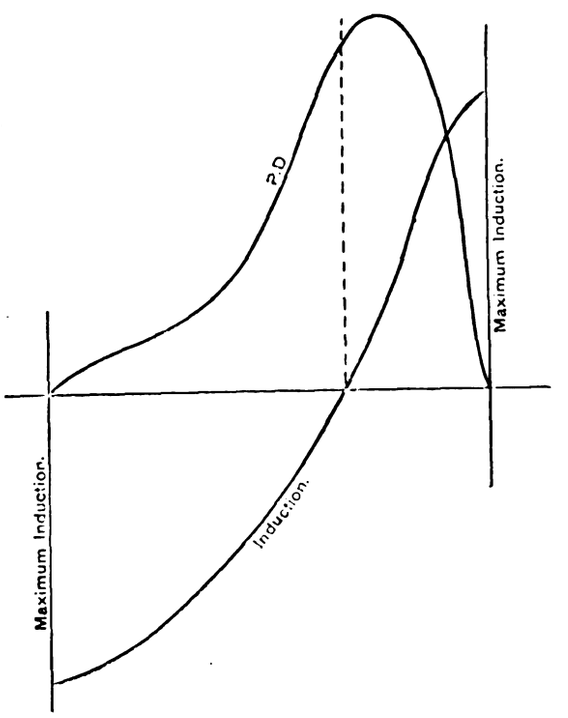

Fig. 2

contact-maker were directly connected with the two slots, while to the small holes were led wires from the terminals of the transformer and the non-inductive resistance R, or from any points in the circuit between which we wished to find the instantaneous value of P.D. As a matter of fact, the terminals of the "injector" were also connected with a pair of holes in the change-over switch A; but these wires are not shown in the diagram, as the graph obtainable at these points was not always taken, and it did not form an essential part of the transformer test.

The value of the non-inductive resistance was 4·15 ohms, so that the maximum reading for obtaining the current-wave was about 16 volts, whereas the maximum ordinate of some of our P.D. curves was as high as 100 volts. In order, therefore, to use the full range of the electrometer in each case, it was necessary to change the potential to which the quarter-cylinders were charged; hence for the P.D. wave we used six cells between the opposite pairs of quarter-cylinders, and for the current-wave 30 cells, the middle of either set being connected with the case, as indicated in Fig. 1. This alteration was effected by means of the change-over switch B. An Ayrton and Mather electrostatic voltmeter, V, was used to keep the R.M.S. volts at the terminals of the transformer constant during each test.

*Speed of the Alternator.*—The speed of the alternator, which could be adjusted by means of coned pulleys, was kept constant at 750 revolutions per minute, thus giving a frequency of 100 ∿. No electrometer reading was taken unless the speed, as shown by a

Rungs pneumatic speed indicator, was exactly right. The indicator was checked several times by a revolution counter, and found perfectly accurate.

*Advantages of Open Secondary Tests.*—Since it is now generally admitted that, with the exception of a slight drop due to leakage at high loads, the total iron losses in a transformer are constant at all loads for the same frequency, we made all our tests with open secondary circuit. This method of attacking the subject offers great advantages, because errors caused by the variations of temperature in the iron core and the non-inductive resistance R, due

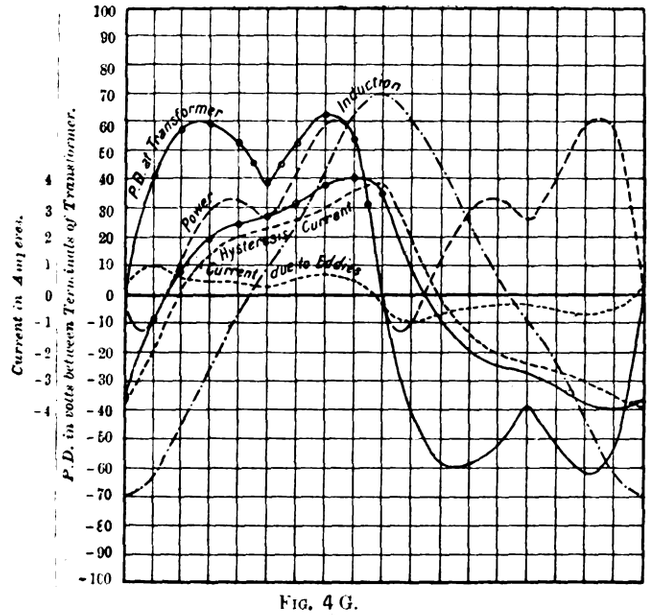

FIG. 4 G.

to the use of different currents, are not introduced into our experiments. In addition to this it will be seen that the working out of our results is somewhat simplified, especially with respect to the determination of the maximum induction. It is in the determination of the iron loss, however, that the method possesses its chief advantages, for we can measure this loss directly, and not as the difference of two much larger quantities. By this means we have been able to find the iron loss accurately to within ½ per cent., which would have been quite impossible with a load on the secondary.

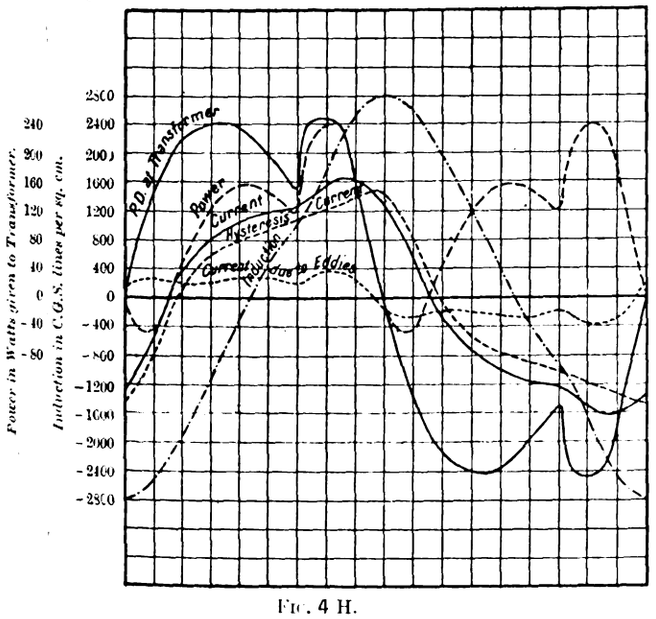

FIG. 4 H.

### DISCUSSION OF CURVES.

All the curves of P.D. and current given in the figures have been obtained by taking the means of the homologous readings on each half-wave. The mean wave thus determined was never found to differ appreciably in any way from the positive or negative half-wave. Each wave was drawn as the observations were made, so that, when the exact contour of the wave appeared doubtful, more readings at points intermediate between those already observed could be *at once* taken and plotted; hence a large number of observations were made on every wave, sometimes as many as 48 points being taken. The normal P.D. wave of the Ferranti alternator (Fig. 4 E), is seen to be very nearly a sine curve, while the current-wave possesses the characteristic deformation always observed when a transformer is working light.

*Induction Waves.*—The induction wave must be found by integrating the curve of back E.M.F. Now in our case the latter is practically identical with the applied P.D. wave, since the drop in pressure due to the resistance of the magnetising coil is neligible. It is interesting to note how smooth the outlines of the induction curves are, even when derived from very distorted waves of potential difference. This point has been fully dealt with by Mr. Evershed in the articles referred to above. We have, therefore, to integrate the P.D. wave; but to do this, we require some starting point, and this must first be found. When the ordinate which divides the half-wave of P.D. into two parts of equal area is known, this presents no difficulty, as the induction must be zero at the point where this ordinate cuts the axis of time. When, however, as is more often the case, we do not know this ordinate, then the above relation will not help us; but there is another relation which is true in every case, viz.: *that the induction must be a maximum when the P.D. is zero.*

It is evident, on reference to Fig. 2, that, according to this relation, the induction must pass from a negative to a positive maximum, or *vice versâ*, during the half-period of the P.D. wave. Since the induction wave is the integral of the P.D. curve, it will also be evident from Fig. 2 that *the area of the semi-wave of P.D.*, multiplied by the required constant, will give twice the maximum induction. (This constant must contain the number of turns in the magnetising coil and the cross section of the iron core.) Thus in every case we can get a starting point for the induction curve by setting up the maximum induction at the point where the P.D. is zero. The wave is then drawn by integrating the P.D. curve in steps from this point, and subtracting the inductions thus obtained from the maximum value. This direct relation between the maximum induction and the area of the P.D. wave is of the greatest importance, for it is evident then that the *amount of hysteresis loss* for different shapes of applied P.D. waves will depend only on the *areas of these waves.*

*Power Curve.*—The actual mean power supplied to the transformer was determined by finding the products of corresponding instantaneous values of the applied P.D. and current. The products thus found were plotted as curves (Figs. 3 and 4), which were then integrated with a planimeter, and the mean ordinate determined. This then gave us the input, and, since the copper loss was negligible—being less than one-fifth of a watt—it represented with sufficient accuracy for our purpose the total watts lost in the iron core of the transformer.

(*To be continued.*)

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**(To-day) FRIDAY, May 15th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*5 p.m.* Students' visit to the Robertson Incandescent Lamp Factory, Brook Green, Hammersmith.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Cable Laying on the Amazon River," by Alexander Siemens.

**MONDAY, May 18th.**

SOCIETY OF ARTS.

*8 p.m.* Cantor Lecture IV.: "Applied Electro-Chemistry," by James Swinburne.

**TUESDAY, May 19th.**

ROYAL INSTITUTION.

*3 p.m.* Afternoon Lecture (III.): "Ripples in Air and Water," by C. Vernon Boys, F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Ordinary Meeting. The following Papers to be submitted for discussion: (1) "The Magnetic Testing of Iron and Steel," by Prof. J. A. Ewing, F.R.S.; (2) "Magnetic Data of Iron and Steel," by H. F. Parshall.

**FRIDAY, May 22nd.**

PHYSICAL SOCIETY.

*5 p.m.* Meeting at Burlington House. Adjourned discussion on Messrs. Frith and Rodgers' Paper: "On the True Resistance of the Electric Arc." The following Papers will be read: (1) "On Dielectrics," by R. Appleyard; (2) "The Field of an Elliptical Current," by J. Viriamu Jones; (3) "An Instrument to measure Frequency," by A. Campbell.

INSTITUTION OF ELECTRICAL ENGINEERS.

*8 p.m.* Students' Meeting at 25, Great George-street, S.W. Paper to be read: "The X-Ray Photography," by H. S. Tyson-Wolff.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Hysteresis," by Prof. J. A. Ewing, F.R.S.

# The Electrician.

**The Oldest Electrical Journal (1861—1878.)**

**Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny.**
**Editorial, Publishing and Printing Offices,**

**1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.**

*Telephone No.* 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

*All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher,* "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

*All Editorial letters to be addressed to the Editor.*

*All letters intended for insertion in* "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

*New Volumes of* "THE ELECTRICIAN" *commence in May and November.*

**Subscription Rates.**—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

| | Year. | Half-Year. | Quarter. |
|---|---|---|---|
| United Kingdom ..... | 26s. 0d. | 13s. 6d. | 7s. 0d. |
| Postal Union ..... | 30s. 0d. | 16s. 0d. | 8s. 0d. |

(Post free, payable in advance.)

## TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

*Advertisement Rates, &c., forwarded on application to the Publisher.*

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* 4 *p.m. on Thursday.*

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications can be ordered direct of* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

**ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced).** Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

**ELECTROMAGNETIC THEORY.** By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

**THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE.** By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

**ELECTRIC LAMPS AND ELECTRIC LIGHTING.** By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

**MAGNETIC INDUCTION IN IRON AND OTHER METALS.** By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

**ELECTRIC MOTIVE POWER.** By A. T. SNELL. 10s. 6d.

**THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical).** By Dr. GEORGE GORE. Price 10s. 6d., post free

**ELECTRO-CHEMISTRY.** By Dr. GEORGE GORE. Price 2s., post free.

**PRACTICAL NOTES FOR ELECTRICAL STUDENTS.** By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free

**DRUM ARMATURES AND COMMUTATORS (Theory and Practice).** By F. M. WEYMOUTH. Price 7s. 6d., post free.

**THE INCANDESCENT LAMP AND ITS MANUFACTURE.** By GILBERT S. RAM. Price 7s. 6d., post free 8s.

**A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ.** By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

**"THE ELECTRICIAN" PRIMERS.** In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

**THE WORK OF HERTZ.** By Dr. O. J. LODGE. Price 2s. 6d.

**A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c** By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

**THE MANUFACTURE OF ELECTRIC LIGHT CARBONS.** A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

**THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS.** Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

**SUBMARINE CABLE LAYING AND REPAIRING.** By H. D. WILKINSON. [*Nearly ready.*

**MOTIVE POWER AND GEARING.** By E. TREMLETT CARTER. [*In preparation.*

**FULL CATALOGUE POST FREE ON APPLICATION.**

## STEEL-PLATE PORTRAITS

*Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field: Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; Dr. Heinrich Hertz; Mr. R. E. B. Crompton; William Sturgeon; and Dr. John Hopkinson, F.R.S., have been issued as Supplements to* "THE ELECTRICIAN."

*Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.)*

## THE JAMES FORREST LECTURE.

The title of Prof. KENNEDY's lecture was not altogether in keeping with the substance. When a man is asked to tell a story, and he replies that he cannot tell a story, but he will sing a song, we let him sing his song, and we give him our best thanks. Prof. KENNEDY has sung his song, and a very good song it is, a song that is getting more and more popular every day, and there is just the chance that it may get too popular, and be sung about the streets with bad voices and bad accompaniment. But we cannot hear the song too often from men like Prof. KENNEDY, and it cannot be too often sung in the lecture-room of the Institution of Civil Engineers. The lecture was not upon "Physical Experiment in Relation to Engineering," but upon "Measurement in Engineering." Electrical engineers need no telling that in their profession it is necessary to know that two and three make five and not six or four; but many engineers do need to have statements of this kind repeated to them. Prof. KENNEDY expressly states that he wishes to regard "mechanics" as a part of physics, and he evidently includes chemistry and all other parts of natural science which in any way relate to engineering. He made a careful and proper distinction between the measurement work of the physicist and the mere metering work of the engineer: "Purely physical experiment is necessary to supply us with most of our important constants, whether connected with the thermal properties of steam, the electromotive force of a Clark cell, the density of water, the elasticity of steel, the coefficient for a *vena contracta*"; and he points out that "the first work of the physicist dealing with his problem is, in fact, to find out a way of so isolating his question that its solution may give

Digitized by Google

him exactly the one quantity he wishes to know, and no other," and he declares that the problem of the scientific engineer is a very much more complex one.

We have ourselves often pointed out that an engineer's problems involve physical quantities in a rather complicated fashion, as something known to everybody but not sufficiently reflected on. For example, there is almost no practical mechanical problem which can be exactly solved by calculation. The mathematical physicist takes a problem involving twenty variables, rejects all but two or three, and gives a result which to some extent can bear to be illustrated by experiment. This hypothetical result is called *theory*. The young engineer is apt to forget that the problem has been simplified, so that what we mean by saying that he is gaining experience is really that he is finding out the proper method of using his hypothetical results in actual work. He calls it exercising his common sense. The man who when he finds that his hypothetical result does not represent an actual problem, rejects the mathematics altogether, is just as unfortunate as the man who never makes the discovery, and indeed each of them is a bad example to the other. When will our teachers give lessons in the use of theory? To reject all but a few of the more important variables, and know what your result really means, or know how to find out by experiment what it means, and so find whether such a method of calculation may be employed in future; and, after rejecting terms before applying his mathematics, to have the wisdom to reject insignificant terms in the progress of the reasoning. To know that pages of mathematical calculation may be saved by using approximately correct simple terms instead of complicated expressions. What is all this but the result of experience—the exercise of common sense?

We do not think that the measurements of the engineer are necessarily difficult ones to make, nor ought his methods to be essentially different from those of the laboratory physicist. He also has, in solving a problem, to isolate it as much as possible from its surroundings, and his object is to give him as exactly as possible the quantity he wishes to know. He also has to try to evaluate unavoidable errors.

It seems to us that the great difference between the engineer's problem and that of the physicist lies in this, that the physicist obtains results which may be repeated over and over again with the same results, by himself or others, whereas the engineer recognises the fact that it is almost impossible to exactly reproduce all his conditions again. And this is why it is so stupid to give results to six significant figures. Prof. KENNEDY in laughing at this stupidity says that although four figures may be useful in mere arithmetical checking three figures are sufficient for results. We must congratulate him if he finds that he can conscientiously give his results of steam engine measurement in three figures, and we are not surprised that he finds the calibration of indicator springs a weariness to the flesh. Less experienced men will probably be satisfied to give only two figures in their answer, and their lot is a happy one if they feel quite certain about the second of those two.

An engineer takes a machine as a whole and makes measurments of certain physical quantities. He can hardly be said to experiment with it. In dealing with his results he uses arithmetic to five or to only three significant figures. In taking temperature he may use a thermometer graduated to the one-hundredth of a degree or only to a degree; he will, both in his arithmetic and his thermometry exercise common sense and waste no effort in an absurd pretence of greater accuracy than the whole problem admits of, but he will also have to get what accuracy is necessary. Experience shows that he obtains results which are of real value in improving his machine or the ways in which it is to be used. Furthermore, the important lesson is learnt that however complicated a machine may be in its construction, in however complicated a way the principles of physics enter into the detailed explanation of its working, there are certain quite simple results or laws obtainable from the engineer's experiments. For example, in a complicated machine where the mechanism may be of elastic and inelastic solid and fluid materials, where friction occurs at millions of places, where the motions are of millions of kinds, where lubrication is as varied as possible, we can rely upon there being a simple relation between energy given to the machine and energy given out by it. Just as good an illustration is afforded by the Willans' rule connecting the weight of steam per hour and the indicated horse-power of a steam engine. The complexity of behaviour in an individual, and the simplicity of law in the behaviour of a society; the complexity of political and social movement in a decade, and the simplicity of the movement when 500 years are studied, these are social phenomena which can be traced to the same causes.

In minor points we differ from the lecturer. An engineering student ought never to think that he is engaged on rough exercises, and, however rough his apparatus, he ought to be taught that he is to obtain notions of its behaviour which are as exact as possible, and notions of the limits of this exactness. There is the old sneer at the interfering physicist and the old cry of the practical man to be let alone as he knows his own business best. Happily he is not to be let alone, and whatever of truth there is in the criticism of outsiders will gradually get to be recognised as such by practical men. But, on the whole, the lecture was worthy of the series and worthy of the lecturer's reputation, and much greater praise cannot be given.

## PHYSICAL EXPERIMENT IN RELATION TO ENGINEERING.*

BY PROF. A. B. W. KENNEDY, F.R.S., M.INST.C.E.

It has been the expressed wish of the gentleman in whose honour the "James Forrest" lectures have been instituted, that they should deal with the relation of various sciences to our own profession. To those of us (and they are many) who have long enjoyed his friendship, and who are to some extent familiar with the extent to which our profession is in his debt in matters innumerable, it is practically a duty to meet his wishes in such a matter. But it must be acknowledged that the duty—as regards the lecturer—must grow every year more difficult, as the field becomes limited by his predecessors; and even at present it was with no little nervousness as to the selection of a subject that I accepted last year the invitation to give this lecture in 1896.

There is perhaps no science, except those in the biological group, of which it might not be argued, with some degree of plausibility and reasonability, that the profession to which we all belong was a direct application. The sciences of mathematics and of physics, of chemistry and of geology, concern themselves with the exact statement of the nature and relations of facts and phenomena with which we as engineers have continually to concern ourselves. But the points of view of the purely scientific investigator and of the engineer, in regard to these facts and phenomena, are no doubt very different. In rare and exceptional cases, one man can play both *rôles*, but this happens so very seldom that for all practical purposes they may be regarded as distinct from each other. And no one who is not terribly narrow—on one side or the other—would deny that either might form a worthy life-work for any man, however high his aims or ambition.

* "James Forrest" Lecture, delivered before the Institution of Civil Engineers, May 7th.

Digitized by Google

I excepted just now the biological sciences from those with which engineers were directly in touch. But, in spite of this, I confess that I have had a great wish for years past to devote some time to the working out of a theory of evolution in relation to engineering progress. I cannot help thinking that there is something in relation to things inorganic which closely resembles the position of natural selection in the organic world. The struggle for existence, which too obviously exists among engineers themselves regarded as organic beings, seems also to exist in effect among engineering productions. There is also among them a survival of the fittest, and the laws which determine what is the fittest at any time, and how the standard of fitness alters as time goes on, are probably capable of fairly exact statement—in correlation with the laws of general human progress; at any rate, they are very well worthy of examination. This biologico-engineering investigation would be no doubt rendered more difficult by the fact that artificial selection continually comes in to help and accelerate, or it may be to hamper and impede, but in any case to modify, the inorganic equivalent of natural selection. I have found this whole subject a most tempting one, full of fascination, and to some extent also of surprises. But finally I felt constrained to leave it, at least as far as this lecture is concerned, to someone—some fortunate person—whose mind was not so overcrowded with the innumerable details of everyday work as my own, or who was able, in spite of these details, to obtain at the same time a broad and comprehensive view of the whole subject from a point higher and more commanding than any that I seemed able to attain to. I hope that in some future year I may have the pleasure of listening to a "James Forrest" lecture in which "Evolution in Engineering" may be adequately dealt with. For myself, I have found it necessary to be content with a much more limited subject, although one perhaps on which my own work gives me more right to speak, "Physical Experiment in Relation to Engineering."

We are all at this present time so familiar with the idea of physical laboratories—places in which physical experiment is carried out systematically and continuously, both for purposes of scientific investigation and of education—that it is hard to realise how very modern an institution the physical laboratory is. Until quite lately the most distinguished investigators worked in laboratories which they had made for themselves and which were essentially their own private studies. The Royal Institution laboratories—originally, I think, rather chemical than physical in conception—nevertheless became to a great extent physical, and in this way were early and notable extensions of the purely private laboratory, and happily exist still to furnish admirable physical work. But it is practically only within the last 30 years that physical laboratories, as we know them to-day, have come into existence. Thanks very much to this growth of experimental and physical teaching, we have now an army of trained physical investigators distributed all over the country, whose principal occupation (besides teaching) is the making of researches in experimental physics, and in this way contributing to our knowledge of the phenomena of the world around us—the phenomena which it is our business to turn to the "use and convenience of man." Not only this, but within the last 20 years there have come into existence numerous well-equipped engineering laboratories in connection with our technical colleges and schools. These engineering laboratories are, of course, simply physical laboratories modified in a certain special direction for our special purposes, and the investigations carried on in them are of the nature of physical experiment as fully and completely as those which are carried out in physical laboratories proper. The aim and scope of the two classes of experiment, however, differ considerably, as do their relations to our own work, and it will be my object this evening to put before you what, according to my own view, are the relations between these classes of experiments, and especially between each class and our own work. I need hardly say that I am bound to look at the whole matter throughout from the point of view of the engineer. I do not for a moment pretend that I am capable and taking up the position of the physicist, and of course I keep in mind also that I have to speak to an audience consisting essentially of engineers, and not of physicists.

Physical experiment, so far as it has relation to our own profession, may fairly be considered to serve three distinct purposes. In the first place, from the purely academic or educational point of view, it is most important and helpful in the training of engineering students. (And it is well to remember that although a great many of us never were engineering students, nor had any opportunity of obtaining such training, yet the most conservative must now recognise that in the future our sons and successors must look on the student stage as being as essential as the pupilage or the apprenticeship.) Then, secondly, what may be called purely physical experiment is necessary to supply us with most of our important constants, whether connected with the thermal properties of steam, the electromotive force of a Clark cell, the density of water, the elasticity of steel, the coefficient for a *vena contracta*, or a thousand other matters of a similar nature. Lastly, technical experiments, which are essentially physical experiments, but of a much more complex nature than those of the physical laboratory (although not on that account more difficult to carry out) are necessary for determining many matters—such, for example, as the efficiency of a dynamo, the steam consumption of an engine, the flow of a river, the resistance of a ship, or even the deflection of a girder under a moving load.

Let us consider, in the first place, the purely educative or academic type of experiment. Here the first requirement is the very simple one—which indeed may be served by an endless variety of experiments extending far beyond the limit of physics—that the student should learn first to see and to measure, and then to write down what he has seen and measured. (Anyone who has had to do with laboratory work knows very well how necessary it is to differentiate in this fashion). The experiments require to be, as far as possible, quantitative rather than merely qualitative; but, otherwise, the simpler they are the better. It is unnecessary here to go into any details about them, but with a view to emphasising their importance it is worth while just to look for a moment at the sort of thing by which, in actual engineering work, these simple experiments may be said to be represented. Perhaps those whose work lies greatly in experimentation, like my own, know best how very hard it is to find assistants, unless they have been trained in a laboratory, who can be trusted at first even to take quarter-hourly readings of a steam gauge or a counter, or any such duty, ridiculously simple and easy as it appears. To ask an untrained man to count the revolutions of an engine which has no continuous counter attached, or to read the dials of an ampere-hour meter, at exactly regular intervals of time, is merely to court disaster! The story is familiar of how Robert Houdin had so trained his faculty of general observation that one look at a shop window would impress its contents on his mind more vividly and accurately than 10 minutes of hard looking would do in the case of an ordinary man. It is really just the same with the simplest of our observations. The ordinary mind does not naturally and at once see, and see accurately, the simplest thing that is before the eyes. One has to look to exercise conscious mental effort, as well as merely to see, and we all of us require to be taught how to look, even in these most simple matters. And when the enforced looking has to be done at exactly a particular time and no other, the average mind is apt to find the whole process an intolerable burden, all the more because it is inclined to despise the work as being too childishly easy for consideration at the very time when it is failing to carry it out!

So far as concerns the training of the faculties of observation at the stage of which I am speaking, probably chemical experiments would serve as well as physical. In certain respects possibly they might even be better, but with this we need not now concern ourselves. An important point is, perhaps, that in their earlier stages the student should not be allowed in any way to get the notion that his experiments are more than mere rough exercises. Any standard of accuracy which he can possibly attain is comparatively a very low one, and by the nature of the case the experiments he can do must be simplified down enormously before they can be put into his

Digitized by Google

hands, so that at best he is only making a rough determination of one element in an artificially simplified operation, the full conditions of which he is not even in any position to understand. The actual figures which are obtained by him can under no circumstances be regarded as having any intrinsic value; and one of the difficulties of the case is, no doubt, to persuade the student to exercise his highest degree of care in obtaining results, which at the same time he is told, or knows, are of no use whatever. The engineering student, I am sorry to say, is generally a terrible utilitarian. The unhappy professor has to enter into all kinds of subterfuges to get him to take an interest in, or do any careful work at, matters which the omniscience of youth has once pronounced to be "useless." Later on, of course, he is wiser and a trifle less narrow-minded; but I suppose the stage of first-yearness is one through which all of us have to pass in one fashion or another, to the grief of our pastors and masters, and to our own later regret.

More interesting to most of us, perhaps, than this purely academic matter is the consideration of physical experiment under the last two headings which I have mentioned.

First among these comes experiment which really belongs to pure physics, but in which we engineers may claim to be as much, or even more, concerned than the physicists, although both the difficulty and the honour of the experiment must fall to them. I suggest that we are even more concerned than the workers in pure science for two reasons, of which the first is that the whole of our interest is practically concentrated on what constitutes only a small part of the boundless region open to the physicist. He can spread his affections over glass and sealing-wax, and let them roam from ice to iron. We have only one love, or at any rate never stray very far from a limited number of matters which concern what I have heard contemptuously called "technical materials." He interests himself legitimately and equally in argon and carbon, in steam and in ethyl-alcohol; he loves to extend his thermal conditions so as to get liquid air or gaseous carbon. We, on the other hand, are compelled to deal with a very small number of materials, and with these materials only in states in which we can readily obtain them. In fact, as every one knows, nineteen-twentieths of our liquid and gas problems affect only liquid and gaseous (or vaporous) water, and only the remaining small percentage is left to be distributed between coal-gas and producer-gas, liquid carbonic acid and anhydrous ammonia, and so forth. So far as the more or less "permanent" gases are considered, our interest is throughout perhaps rather chemical than physical.

Then, again, we may claim to have a first interest in certain physical results, because of the extraordinary frequency with which we have somehow or other actually to make use of them—I mean a real live use, and not merely a use in an examination question, or in a text-book or a lecture. Not only would our whole work become mere guess work without the knowledge of these results, but, having this knowledge, we are compelled by the very nature of our work to make such continual use of it that probably we are much more familiar both with the figures concerned and with the phenomena which they represent, than even the men to whose magnificent accuracy and unlimited diligence we owe their original investigation and determination. I mean, of course, such results as refer to the thermal relations of water and steam, to the calorimetry of fuels generally, to many hydrodynamic problems, to most problems in elasticity and what is clumsily called the strength of materials, to frictional questions, to innumerable problems relating to electrical matters, and certainly to an enormous number of matters bearing on mechanics, which, of course, is to be considered as a branch of physics.

I feel so strongly this sense of our paramount interest in certain physical problems that I have not hesitated sometimes to resent the way in which physical writers and speakers are occasionally inclined to instruct us how to express our ideas, for example, as to mass and weight, and sundry vital matters of that kind. I really think that people who have to deal with these matters as much, as often, and as thoroughly as we have, and who are on the whole reasonably competent beings, may be assumed to know how best to manage our own affairs in these respects. Mechanics are to us the breath of our nostrils, and not a mere vehicle for examination papers; and it should be remembered that the requirements of the latter case may be very different from those of what I may venture to call "real life." I feel some satisfaction in remembering that the only fatal case of a misused "$g$" that I can call to mind was on the part of a physicist, whom we all admire none the less for the way in which he scolds us, but who, in the very act of showing us the way we ought to use that symbol, proved conclusively that all submarine cables would break by their own tension while lying on the sea-bottom! It would, perhaps, be hardly proper, or even safe, that I should here say anything, as I am much tempted to do, as to the vexed question of units, which from time to time seems to agitate many minds. Let me only suggest that, on the whole, it does not seem to me that the people who would be most affected by the change are at present those who are most anxious for it. In fact, admitting certainly a few notable and very distinguished exceptions, it really seems as if engineers in general were content to go on in their own way, unconscious of the terrible pitfalls and difficulties by which it is understood that they are surrounded on all hands. I quite admit, of course, that it by no means follows that the pitfalls do not exist, although I confess to being somewhat sceptical about their reality.

But having spoken so strongly of engineers as being the users of certain physical results, I must look at the other side of the matter. We engineers may have, as I urge, more interest in these matters than anyone else, but it is certainly true that we have not ourselves to thank for the determination of the results which we require and which we make so much use of. For practically the whole of these results—results without which, as I have said, our profession would hardly exist, would at best be a mere trade instead of (as we are proud to consider it) a scientific profession—we are indebted to workers in physical science pure and simple, men without the least taint or suspicion of technical or utilitarian intent.* It would therefore ill become us engineers if we were to say or do anything which should, even in a most indirect fashion, tend to belittle the work of pure physicists, on which every day shows us more how much we are dependent. Our gratitude is so real and so deeply seated that we need not, and do not, even resent the expression of regret which has sometimes been heard from a discoverer, that what he has done should be of any use whatever!

A physical experiment such as is necessary for the determination of any one of the physical constants which we have in continual use differs very essentially from such physical experiments as we engineers have to carry out in the course of our own work. It is at once much simpler and much more difficult. It is simpler, because its object is the solution of one certain problem, which has been by much care and pains isolated from all its surroundings, from all related and, so to speak, adjacent problems. The first work of the physicist, dealing with his problem, is, in fact, to find out a way of so isolating his question that its solution may give him exactly the one quantity he wishes to know and no other. Of problems of this kind I confess I speak as an outsider; but as an outsider it has been to me often a matter of the greatest interest, and even wonderment, to see what enormous pains a physicist takes, and must necessarily take, to make sure that he is measuring exactly the thing he wishes to measure—that thing, that whole thing, and nothing but that thing; to see also what innumerable precautions he has to take to ensure the absence of minute errors, or to find out where any such errors might occur, and whether they have occurred, and to evaluate them if they are unavoidable. I have found, too, that in such cases suggestions derived from my own experience in engineering experiment have been often received with a coldness which I am afraid was no more than they may have deserved! For, as I shall endeavour to show, the conditions under which

* I think probably the only notable exception to be made in this matter is in regard to scientific experiments relating to strength and elasticity, some of which have been made by engineers and with a more or less definitely technical intention. But probably such men as Bauschinger, Martens and Tetmajer are to be considered essentially as in the position of physical workers.

Digitized by Google

experiments of this kind have to be made are absolutely different, both as to aim and method, from those of the experiments—more technical if not less physical—which we have to carry out for ourselves in our own work.

In a physical experiment of the second category, such as those of which I have been speaking, the primary points may be said to be, first, that the object of the experiment should be single, definite, isolated, separable and separated from all surroundings; secondly, that it should be general in its nature, and should not relate merely to one special case; next, that as a problem it should be capable of exact determination; and lastly, that the final result should be as nearly absolutely accurate as it is possible for any physical determination to be. Take as examples such matters as the determination of the density of steam, of the variation of the specific heat of water with change of temperature, of the calorific value of pure carbon, or of the mechanical equivalent of heat. Such problems properly stated admit each of one exact solution, one answer which is absolutely right, even in the mathematical sense of that phrase. It is the highest object of the physicist, in dealing with such a problem, to obtain the right solution. He spares no pains to obtain it, he determines each minute correction with the patience and care of a man who knows that the value of his whole work may be vitiated by a single overlooked source of error, even of the smallest magnitude. We engineers are possibly in some danger of forgetting occasionally, in view of the familiarity and matter-of-courseness of certain figures with which we have frequently to deal, that just these everyday and familiar numbers, on account of their very importance, were those which required and obtained for their determination the most careful, exhaustive, and accurate experimentation in the hands of the most experienced physicists.

After speaking in this fashion of the nature of experiments in pure physics, it may sound at first absurd, but it is nevertheless true, to say that physical experiments in the third category—the technical experiments which we engineers have so often actually to carry out—do not fall under a single one of the conditions which I have just given as characteristic of experiments in pure physics. We cannot, even under the most favourable circumstances, put before ourselves exact and isolated problems; we have much more often to deal with special than with general cases; we cannot choose problems which are capable of finally exact solution; and, therefore, lastly, we should treat the matter entirely wrongly if we attempted to obtain more than a certain limited degree of accuracy in our solution—an accuracy very limited indeed when compared with the all but mathematical accuracy with which problems in pure physics can be solved.

The conditions under which engineers have to carry out physical experiments, of course, vary very greatly. In certain simple cases they are essentially physical investigations, be it in connection with friction, with elasticity, or what not, which at first sight do not greatly differ from the experiments which I have just discussed. There is probably, however, more difference than appears at first sight, although the spirit in which both sets of experiments have to be made is the same. Take as an example the determination of the elastic modulus (or the specific extension) of a piece of steel. Probably, with very perfect instruments and with extreme care in manipulation, a value of the modulus could be obtained which should be accurate, say within 1 in 2,000, for that particular piece of steel. But a figure so obtained would not be accurate even for other pieces of steel made at the same time, and out of the same ingot as the one experimented on; while, of course, there is no one absolute value for the modulus of elasticity of the widely-differing material of which all sorts go by the name of steel. Under such conditions—and I have chosen a particularly favourable example—it would be mere affectation, and, in addition, would be actually misleading, to claim anything like physical accuracy for our results. Indeed, I must go further and say that the truly scientific way of treating an experiment in engineering physics is to recognise from the outset its limitations as to accuracy, and to be careful not to state a final result in a form which should lead to the supposition of any greater degree of accuracy than that which the conditions of the work can actually allow.

The difference between physical and technical experiments may easily be illustrated by another example from the region of elasticity. The determination of the deflection of a beam, transversely loaded, as a physical experiment would resolve itself into the test of the behaviour of a piece of homogeneous material, preferably of the simplest possible cross-section, probably rectangular. It would be a matter of importance to ensure that the material was exactly of a certain chemical nature, and that it was mechanically free even from the slightest defects; it would also have to be machined to certain exact dimensions. Even with every care, the almost unavoidable imperfections in the material, minute variations in uniformity of structure, and so on, would be very difficult to deal with and to allow for. As a technical experiment, on the other hand, the beam might consist of plate and angle irons secured together by rivets, the whole forming a structure with absolutely no pretence to homogeneity, nor to absolute exactness of dimension. Its rough surface would be carefully left intact, and not in any way machined, its riveted parts would be brought together as well as was reasonably possible with the appliances at the command of the engineer, but without any attempt to make a special fit between surfaces. In fact, the whole thing would be constructed in imitation of the way in which a riveted beam, such as is used as a girder, is usually made. The result obtained would obviously not be a general one applicable to steel as a material, or to beams as geometrical forms, because the data of the problem, even the dimensions of the beam itself, could not be determined with minute accuracy, nor would the actual final result be comparable in accuracy with the determination of the similar problem treated from the purely physical point of view. Hence, as the experienter cannot for a moment pretend, and should not for a moment delude himself into supposing, that his results could be more accurate than his data, it is his first duty in this line of work to find out within what limits of accuracy his experiment can be carried out, and, when he has obtained his results, to state it only within these limits. Under these conditions the statement of a result in round figures is often much more accurate that its statement down to the last decimal place which appears in the arithmetic. I have heard it said by some of the students of the greatest of our physicists, Lord Kelvin, that this was a point upon which, even in a great deal of purely physical work, their master always insisted most strongly. But I am afraid that it must be admitted, as a weakness of much of our engineering experimentation, that its results are given in figures which are absolutely ludicrous as indicating the value of the quantities actually measured. In these matters, perhaps, our friends in America are even worse than we are, and those of us who have anything to do with steam vessels or with steamship trials, are perhaps the worst sinners. I suppose no physical problem could very well be much more complicated than that (I ought rather to say those) involved in the carrying out of a marine-engine trial at sea, especially when power and speed are both concerned. When it is considered that the final result depends on the accuracy of our knowledge of the dimensions of the steam engine itself, and of the steam engine indicators, on the uniformity of elasticity and proper scale of the indicator springs, the accuracy with which the revolutions are observed, the accuracy of timing on the mile and of observing the distance at the same time, to say nothing of the assumption that the indicators themselves and their gear, unlike every other thing in the universe, are entirely devoid of hysteresis, it will be seen how entirely out of the question it is that the figures obtained, even for a single run in one direction, should admit of statement in, say, more than three figures. When to this is added the uncertainty of the method of averaging speed as between a number of runs under different conditions as to tide and wind, the matter becomes still more striking. Or, when coal and water are also to be measured, and the weighing or measuring of both, and the calibration of all the heavy apparatus used for the purpose, as well as the personal errors due to making observations of large quantities under awkward physical conditions, in a minimum of time and in the worst of atmospheres, are considered, the uselessness and indeed the absolute inaccuracy of extremely minute figures

Digitized by Google

become absolutely glaring It is sometimes useful, no doubt, under these conditions, to work out results to four significant figures for the sake of mere arithmetical checking; but no one who has had anything to do with the matter would suppose for a moment that more than three figures were of the least importance and the statement of results of observations in five or six figures merely causes the enemy to scoff. Let me again say here that I am not suggesting, and I do not think, that an experiment of a technical nature is unscientific because its result is only capable of expression within 1 or 2 per cent. instead of within one or two hundredths per cent. I wish only to urge very strongly that in a really scientific spirit such an experiment must be undertaken only with a distinct recognition of its limitations, and of the limitations of accuracy of result such as I have roughly indicated.

But I must claim for technical experiment that it is truly scientific work if only it be conducted with full recognition of its conditions and limitations, and not as if it were a laboratory experiment badly done—a mistake which I fear is too often made. Let it be recognised first of all that our object is generally the determination of certain facts, or quantities, or ratios, which are to be found under certain very complex conditions. As I have elsewhere said, the duty of the engineer is to recognise these conditions and deliberately to include certain of them in his experiment. The physicist has to spend much thought and trouble on the modification of conditions, which are disturbing elements in his work. All conditions which might justify his main result, or which might make it difficult for another experimenter to obtain precisely the same value for the quantity looked for, have to be either eliminated or evaluated. The conditions are his enemies, in fact. Otherwise with us, the conditions in general form part of our problem, and for many purposes the reduction of the experiment to its lowest terms, which is the object of the physicist, would not only be impossible, but would, if it could be done, make the result quite useless to us.

The determination of the efficiency of a steam engine is, of course, a very common piece of work, and may serve as an illustration of the two different ways of approaching such a matter in connection with this question of conditions. From the physical point of view, I imagine it would be best to endeavour to reproduce the working of the much-abused Carnot cycle.* If this were absolutely successful it would merely gave us a result which would agree with those which we can already calculate from the physical data which are in our possession, and this result would add nothing to our present knowledge, nor would it give any additional help to the designer of steam engines.† But it would, if it could be carried out, be an experiment strictly physical, and following in the lines of, for instance, Joule's classical experiment on the mechanical equivalent of heat. The engineer, on the other hand, who has to work at the same problem, has to deal with it in the fashion in which it is now handled in so many engineering laboratories. He has to make for himself an actual engine, in which the normal conditions of engine working—as to loss of heat by conduction, condensation, radiation, and so on—are, or can be, reproduced, and he has to make his experiments on this machine, and as nearly as possible under conditions resembling those under which engines normally do work. Then one by one certain of the conditions may be altered, so that some estimation may be made of the effect of each. So may be obtained figures as the result of *bonâ fide* technico-physical experiment, which are also in a form more or less directly applicable to engineering work.

I have just mentioned the variation of conditions one by one. This is hardly a matter which I need insist on. It is of great importance even in a physical experiment, where all the conditions are simplified to the last extent; but in a technical experiment, where the conditions themselves are very complex and often not easy to grasp, it is obviously vital. It is no doubt one of the great difficulties of all technical experiment to find out exactly what the conditions are, and it may in many cases need more experience and more care to determine and define the actual conditions than it does to carry out the measurements involved in the experiment. This is a matter which will be recognised by everyone who has had to do with work of this kind, but about which probably it is unnecessary to say more here. Bearing on it, however, is a matter which may fairly be mentioned, namely, the combining of the results of several technical experiments. This is often very tempting, but is always very difficult. A simple case is, for instance, the determination of the efficiency and of the economy of a steam-engine. A certain experiment may show a certain maximum efficiency; another experiment, on a more or less similar machine, but carried out at another time, may show a maximum economy. Naturally there is a strong temptation to state both maxima as belonging to the machine tested. It is, no doubt, possible that they may do so; but, on the other hand, without the most minute knowledge of the circumstances of the case, it is quite unsafe to assume that they do, and in this respect the difference between the general character of purely physical work and the special character of technical experiment comes into clear relief.

In fact it is much more difficult to handle rightly the results of engineering experiment when they have been determined than those of pure physics. It is by no means always, or obviously, easy to apply these last, at least one has known very ludicrous mistakes to occur through their misapplication. For instance, I have seen elaborate calculations based on the determination of the weight of steam used by an engine from the pressures shown by an indicator card and the measured dimensions of the engine; and quite recently I was confronted with certain supposed phenomena, which rested entirely on the assumption that a vessel of certain dimensions actually received from a steam pipe suddenly opened to it only the weight of steam corresponding to its volume and the pressure shown by a gauge! In both cases the troublesome phenomena of condensation were entirely left out of account, and the result of a purely physical determination was applied to a technical problem with very disastrous results. But it is infinitely more difficult often to interpret and to apply the results of our own experiments. For instance, let it be found that one boiler, engine and dynamo together require the consumption of so many pounds of coal per electrical unit, how much coal per unit will another boiler, engine and dynamo require? Put baldly in this form the question sounds ridiculous. But after all, is it any more absurd than our constant endeavour—that is, before the days of the present development of engineering experiment—to arrive at similar comparative conclusions from the doubtless unimpeachable figures of an engineering pocket-book? I am sure there must be many of us who can still recollect how painfully we endeavoured to make the statements of Molesworth furnish us with an answer to our own problems, and how entirely we failed to get things to fit in. I do not suggest that the fault lay with the pocket-book; the fault lay in the endeavour to correlate figures and results which in no way belonged to each other, which represented the result of experiments made under conditions quite unknown to us, but certainly varying from each other, and no less from the conditions (possibly also unknown to us) of the problem we actually were trying to work out. I dare say that many of us, who have been hungry and thirsty for facts and figures during most of our lives, remember very well the joy with which, at a certain stage, we put down in our note-books any kind of experimental results of which we could hear, or of which we could obtain possession by any means, whether they related to steam engine trials, or to girder tests, or to the discharge over weirs; I do not say to dynamo trials, because there were no dynamos in those days. And I am sure that all of us must have suffered pain and disappointment later on, when we found how extremely difficult it was to make any use of the much-

* I need hardly say that I do not for a moment suggest that any physicist would wish to obtain experimentally a result for which he has already given us all the constants, and which we can therefore completely obtain by calculation based on physical results already before us.

† I do not wish here to be understood in the least as sharing that great objection to the Carnot cycle which I know fills the breasts of some of my friends. It appears to me that it would be just as reasonable to object to the asymptote of a hyperbola or to the line at infinity! We require these limiting cases, and should get on very badly without them, and I am not inclined to say that they are useless—indeed, I think they are extremely useful—although I am perfectly conscious that they represent a state of affairs which is technically, and even physically, unattainable.

Digitized by Google

valued figures that filled our pages—they would never, somehow or other, seem to tell us just what we wanted; there was always something about them which eluded us, one particular matter of vital importance in the data, or in the result, of which we had no memorandum. The fact is that it is always extremely difficult to apply accurately the results of experiments made by others, however carefully made and however accurately described. To realise this, even in reference to purely physical work, one need only see how many pages in the *Philosophical Transactions* are sometimes necessary to describe the methods and precautions involved in a determination which has not one-tenth the complexity of such matters as we are compelled constantly to try to measure.

To anyone who wishes to realise to the full the difficulty of dealing with, or applying, the very simplest kind of experimental result, I recommend the maddening task, so often lightly spoken of by those who have not tried it, of calibrating indicator springs, and then trying to apply the results to the correction of the corresponding indicator diagrams.

The fact is that no one can usefully apply physical results who has not himself studied the methods by which these results are obtained, either by the royal road of work in a physical or technical laboratory, or by the hard and up-hill method of self education in the making of technical experiment without the advantage of the preliminary training which I have mentioned earlier; and hence the importance of the knowledge of how to make accurate observations, which I have insisted upon as a thing quite apart from the knowledge of the actual figures to be obtained by such observations. It would, perhaps, be cruel to say that no one can usefully apply physical results who has not studied the methods by which they are obtained, were it not that nowadays the possibility of such study is open to everybody. One may, therefore, state the truth in this matter without the fear of making anyone unhappy. I do not know whether I should be far wrong in suggesting that a certain amount, perhaps a great deal, of the very rapid improvement which has taken place in late years in engineering practice in respect to efficiency in the working of machinery, economy in the production of energy, and economy also in the use of material, has been due directly or indirectly, or both, to the growth of the habit and knowledge of experiment among the present generation of engineers. No one who is familiar with the progress in such matters as I have this evening dealt with, during the last 20 years, and has noted the extraordinary development which has taken place, can fail to be struck with it. No doubt a considerable part of this development has been due to the better education generally of engineers, and particularly to the great extension of engineering literature in which undoubtedly the engineering newspapers have played a most honourable and important part. But these general causes in themselves would not, I believe, have been sufficient if it had not been for the contemporaneous development of what I may venture to call experimental training, accompanied by a demand on all hands from inventors, manufacturers, and even from the public, for reasonably exact numerical statements in relation to everything which can be measured, instead of the vague generalities which used to pass muster as critical examination of the advantages and disadvantages of any new proposals.

I hope I need not say here that I quite recognise that an engineer's life is not made of experimentation, and that the work of *doing* is even higher than that of *measuring*, at least from our point of view. But in dealing with my subject of to-night, I am, of course, bound to take up and emphasise this aspect of engineering work. I hope that it may be considered that I have been able to justify my choice of a subject which at first might appear so limited, but which in reality I believe so important, as that to which I have addressed myself this evening—the relation of physical experiment to engineering.

**Annual Dinner of the Old Students of King's College.**—This dinner will be held at the Holborn Restaurant on Monday, June 29th. Sir Benjamin Baker has kindly consented to preside.

## ON RAILWAY TELEGRAPHS, WITH SPECIAL REFERENCE TO RECENT IMPROVEMENTS.*

BY W. LANGDON.

*(Concluded from page 57.)*

### Gutta-Percha and Covered-Wire Work.

It is believed there is very little to record in the matter of gutta-percha-covered wire. In making it a practice to use ozokerite taped wire in all instances for underground work or for wooden casing, it is probable the author is merely following the practice of others. The taping adds very little to its cost and very largely to its life. The number of wires which are now required for signalling purposes—the fact that, as a rule, the "leading-in" pole is placed in the rear of the signal box, while the instruments are invariably arranged over the signal lever frame in the front of the box—leads to a large consumption of gutta-percha-covered wire, and renders it all the more necessary that every precaution should be adopted to preserve the life of the insulation. To this end all G.P. wires should be boxed in; and the boxing (which should be grooved from the solid), when carried underneath the floor of the signal box, should be inverted, so that any moisture from the washing of the floor of the signal box may not penetrate the boxing and impair the percha.

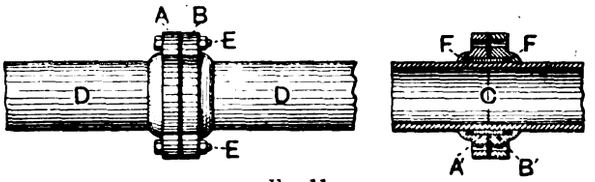

Fig. 11.

The author has for some years employed wire covered with india-rubber, plaited cotton, and compound, for signal posts. It withstands heat much better than G.P., the conducting wire is less liable to become decentralised, and he has good reason to believe that it will prove very durable.

Although instances have arisen where armoured cables composed of from three to ten conducting wires have been employed for telegraph and signal purposes, it cannot be said such are in general use. In station yards, where the wires are generally laid underground, and in other equally crowded places, armoured cables for odd lengths will probably be found not only useful, but in order to avoid disturbing the body of through wires, a necessity. Such cables are extremely useful for crossing the line of railway for repeater, or similar purposes, where, unless the wires are carried underground, a large alteration is necessary in the poles in order to carry them overhead.

In laying down some underground work at Leicester and Nottingham, a simple form of cast-iron piping, which, having an india-rubber joint, is very quickly placed in position, has been used.

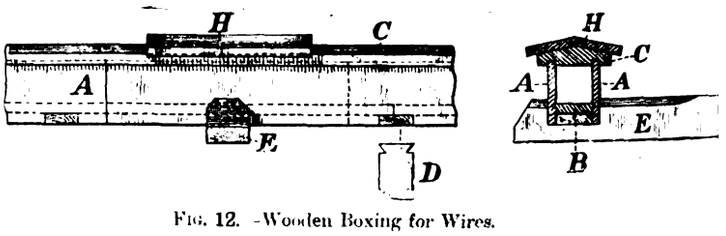

Fig. 12.—Wooden Boxing for Wires.

It is inexpensive and readily handled. An illustration of the joint will be found in Fig. 11. A B are clamps, which slide over the pipe D, which is merely a straight tube. A, B are recessed at A', B', so as to receive the small piece of tubing C, together with an india-rubber washer, $F_1$, at either end. The pipes D are laid out so as to meet at C. A and B, as well as C, are then slipped on, the tube C is brought into its proper position, and A and B are then closed up and tightened by the bolts E. The india-rubber washers afford a firm grip, so that the pipes D are not readily drawn apart. The arrangement is better suited for level ground than for heavy slopes.

Fig. 12 represents a form of wooden boxing for tunnels and wall work. It is the production of my inspector carpenter, Hobday, and is set together and maintained in position without the aid of a nail or screw. It is formed of four pieces of wood. The side pieces, A, A, are grooved to accept the bottom board, B; the top, C, is grooved to accept the side pieces: the two sides are held together by tie-pieces, D, inserted at intervals of 3ft. Instead of iron

* Paper read before the Institution of Electrical Engineers, April 30th.

Digitized by Google

supports wood blocks, cut from flawed or otherwise unsatisfactory oak arms, are shaped as shown by E to receive the boxing. These supports are fixed in the masonry by wood wedges or cement 6ft. apart. A piece of wire passed around the support and the boxing holds the entire structure safely in position. No two pieces of wood from which the boxing is composed terminate at the same point, with the exception of the lid. At the junction of these pieces a wooden capping, H, is employed to cover the seam.

### Instruments.

In telegraph message instruments the vertical handle "single needle" remains that generally used in Great Britain. For some years it has been the practice on the Midland to employ at the transmitting or terminal station of all busy single-needle circuits a "Bright's Bell" in place of the single needle—an arrangement which will be found to aid despatch and lighten the labour of the clerk. The "Bright's Bell" is also largely used by the Great Northern between telegraph offices. The Lancashire and Yorkshire and the Great Eastern employ it on single-needle circuits in a similar manner to the Midland.

Although the "sounder" is very generally employed for railway message work in Ireland, it cannot be said to have taken root on English railways. For direct and long circuits it is occasionally used, but, it is believed, not to any great extent. For "quadruplex" working the demand does not appear to have been very urgent. It is employed by Mr. Hollins on the Great Eastern, between London and Harwich. "Duplex" working is employed on the Great Eastern, Caledonian, London and South-Western, and London and Brighton, and on the Midland. On the Midland a duplex circuit between Derby and London also provides for a phonopore communication. The phonopore is employed to a very limited extent on the Midland, Great Western, Great Eastern, Brighton, and North British lines. Telephones, as was to be anticipated, are now very generally employed for *viva voce* communications between signal boxes, and at busy centres between the administrative offices. That their employment largely aids the disposal of traffic there can be no question. At many points, and under exceptional conditions of weather, they are invaluable.

On the Continent, as well as at home, serious rumours have, from time to time, arisen with respect to the dissemination of disease by means of these instruments. It has been contended that a person suffering from throat or other internal affection, on speaking into a transmitter, may leave in the interstices of the instrument germs of the disease, which may be inhaled by others using the same instrument.

Fig. 13 represents a transmitter which has been designed with a view to obviate any such evil effect. The ordinary mouthpiece is removed, and in its place the entire face of the instrument is covered by a diaphragm, A, made of wood or metal—the former by preference—which encloses an air space, B, between it and the ordinary, or electrical, diaphragm C. On speaking in the neighbourhood of the outer diaphragm its vibrations are transmitted by the pressure of the enclosed air to the electrical diaphragm. Speech is marvellously clear, and only when used for long-distance telephony, as between London and Glasgow, is any diminution in the sound noticed, and then only in a very slight degree.

### Block-Signalling Instruments.

The practice of arranging the block-signalling instruments apart from the signal frame has with most companies been abandoned. As a rule, all block apparatus is now fixed on a shelf immediately over the signal frame, so that they may be readily manipulated by the signalman, and their indications remain present to his view.

With the exception of the introduction of Tyler's tablet block, and Messrs. Webb and Thompson's electric staff for working single lines, there is little of novelty in block instruments to record.

Interlocking the electric with the mechanical signals has made but little progress. The mileage of railway lines in Great Britain* worked under the absolute block is 26,398. A very small fraction of this has the electric signals interlocked with the mechanical signals.

It appears almost marvellous that the enormous traffic which now passes over our railways should be conducted with so few casualties under an arrangement which entails a perfectly independent action for both the electric and the mechanical signals. The former are provided for the regulation of the traffic between signal post and signal post; but where they are not interlocked with the mechanical signals, which are those which actually guide the engine-driver, they merely indicate to the signalman how he is to work his signals; they in no way control them! That so few casualties arise testifies in the highest degree to the care and watchfulness exercised

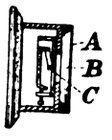

Fig. 13.—Telephone, with Wood Diaphragm.

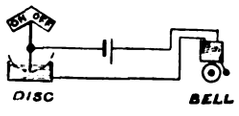

Fig. 14.—Repeater Disc.

by the signalmen to whom falls the duty of working the traffic under such conditions. The subject is one which may well lay claim to further consideration at the hands of some member of this Institution. In the meanwhile, it may be desirable to point out that the interlocking which has so far been employed is still wanting in finality. As now used, it is the first vehicle which releases the lock. Needless to say, it should be the last.

Electric "signal repeaters" and "light indicators" have become indispensable adjuncts. On the Midland there are no less than 3,000 of the former and some 800 of the latter in use, and with many other companies the number is no doubt as large.

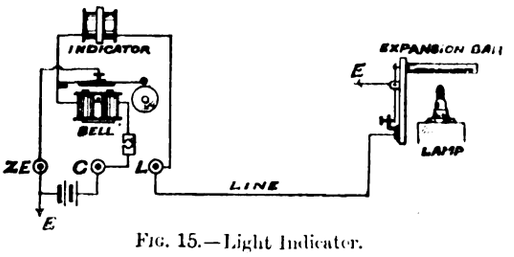

Fig. 15.—Light Indicator.

Another useful adjunct is that termed the "repeater disc," employed to indicate the movement of the lever of "slotted" signals. It differs from the signal repeater in that the indicator, when passing from the ON to the OFF indication, directs the signalman's attention to the alteration by ringing a bell (Fig. 14).

"Light indicators" should be so constructed that they may indicate any failure in the light by a continuous ringing of the bell. This entails the maintenance of the *Light In* signal by permanent current. Two No. 1 Leclanché cells work the instrument perfectly well. Fig. 15 is a diagram of the connections.

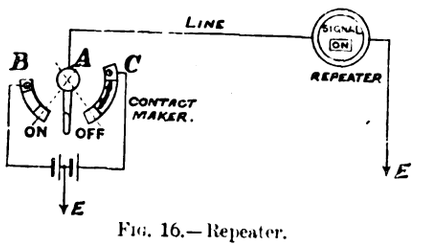

Fig. 16.—Repeater.

Fig. 16 it a diagram of the signal repeater arrangement, the batteries being placed at the signal post. The ON contact B is fixed, and the contact which the tongue-piece A makes with it is only sufficient to admit of a movement of 2deg. The contact C is adjustable. Samples are on the table.

### Batteries.

To the bichromate and Leclanché battery the author ascribes the palm of merit for a good and useful battery for railway purposes. For hard and constant work the former is unsurpassed. For occasional purposes, and for constant action, under certain limitations, the Leclanché commands attention. The old form of Daniell (sulphate of copper) battery, it is assumed, no longer finds a profitable field in railway telegraph work.

The Leclanché-Barbier cell is the latest development of the liquid Leclanché type of battery. It differs from the preceding types in the form of the positive element, together with other mechanical details. The positive element consists of a hollow cylindrical agglomerate of carbon and peroxide of manganese, around the upper part of which is cast a metal ring, caused to fit the neck of the jar, between which and the metal ring an india-rubber washer is inserted. The centre of the cylinder is covered by a wooden block, which serves to support the zinc and to close the jar. There is thus little possibility of evaporation; the cell is practically hermetically closed, and is in every way satisfactory.

The most recent innovation in batteries is the so-called "dry cell," but of them the author cannot profess to any lengthened experience. In their early days they were frequently disappointing and unreliable. Much of that has now been remedied; yet, it is doubtful if their employment in railways would be economical, for it would still be necessary to retain linemen and battery men, or assistant linemen, to attend to failures of instruments, &c., when such arose. General freedom from such failures would in no way modify this demand for the presence of the linemen. Failure at some time would be certain to arise. Whenever it did the lineman must be there promptly to attend to it, or the traffic would necessarily suffer.

I feel that, in submitting to your consideration so lengthy a Paper, I have largely encroached upon your time and patience. It has, however, been impossible for me to deal with the subject in less space, and equally impossible to divide it into two parts. I believe that you will, under these circumstances, generously accord me your kind indulgence. As it is I fear I may still have omitted some points of interest, and that possibly a want of knowledge of that which has been, or is being, done by others may even now render my treatment of the subject incomplete. Where such is the case I must trust to my *confrères* to supply any such deficiency in the discussion which the Paper may elicit.

## DISCUSSION.

Speakers who have returned their proofs revised are denoted by an asterisk.

*Mr. LANGDON read letters from Mr. Graves, of the North-Eastern Railway, and Mr. W. H. Preece. The former said that the first copper wire he erected was in July, 1871, between the Newcastle station yard and the Gateshead yard, and he employed copper wire in a number of other places before the line at York, put up at York in 1877, and alluded to in the Paper as the first. Mr. Preece thought the author was wrong in saying that Mr. Graves was the first to put up copper wire. All the wires erected between Paddington and Slough, the first ever put up, were of copper. The great start in copper was when he (Mr. Preece) induced Mr. Patey to run a copper wire from London to Newcastle, which proved that it not only reduced resistance, but increased capacity, eliminated electromagnetic inertia, and also increased the speed of working. They also introduced copper for the Post Office telephone circuits with the same objects in view.

*Mr. WYLES said he was not prepared to discuss Mr. Langdon's Paper with regard to telegraphic arrangements, because they generally accepted what was done on the Midland Railway as the best that could be done; that was well-known amongst railway telegraph engineers. But the question of interlocking had not been dealt with very far, and Mr. Langdon almost invited another Paper to be read on that subject. He might say that all the congested traffic out of London, at any rate on the southern side, was controlled electrically. On the South-Western Railway, from Waterloo as far as Esher and Twickenham, everything was interlocked, and they were extending that very largely. From Cannon-street to London Bridge on the South Eastern and a considerable way down everything was interlocked; and the same thing was true of the Brighton line and the Great Eastern. On the South-Western especially they were largely called upon to assist the mechanical department by doing a lot of work electrically which could not be done mechanically. Electrical fouling bars were coming very much into use, and were put down by the telegraphic department, but were

always asked for by the mechanical department to assist them in working and to help the traffic and secure greater safety. They had a good many cases where signals were thrown to danger electrically. With regard to single lines, they had an arrangement on the South-Western which was devised by Mr. Sykes – and he (the speaker) had a good deal to say in the matter—by which the starting signals were controlled so that they could not lower the starting signal unless the tablet was drawn.

*Mr. GOLDSTONE thought there was a printer's error in the Paper where there was an allusion to duplex working on the London and South-Western Railway. He thought that was meant to be the London and North-Western, for they had nothing of the kind on the South-Western service. He must also say that he was somewhat surprised to find that so little was being done generally throughout the Kingdom in connection with interlocking. On the South-Western they had at the present moment in use something like 150 miles of electrical interlocking. They had large orders in hand, and he apprehended that by the end of the year quite a third of the line would be interlocked, and certainly all the busy portion of it. As Mr. Wyles remarked, they were also called upon to enable the trains to throw up signals electrically as they passed them; in fact, at no period in his experience had they been making greater progress than at this moment, principally in connection with interlocking.

*Mr. C. E. SPAGNOLETTI said the Paper wanted carefully digesting before it could be discussed properly, but they must compliment Mr. Langdon for giving them so much information, a good deal of which, he had no doubt, was new to the younger members of the Institution. There were one or two points in the Paper that needed a little discussion; and for one thing he rather took exception to the system of poles described by Mr. Langdon in Figs. 1 and 2. The H-pole system, as they called it, had been used for a considerable time, and he thought he could suggest an improvement on Mr. Langdon's method. If they looked at the diagrams they would notice that the cross pieces of the poles were bolted through. If one of these poles were to sink the cross pieces at the bottom of the poles caused a hinge, as it were, on the other pole. It was true the iron cross-piece in the middle of the poles would, to a certain extent, stop sinking, and also the cross-arms; but it would put a very heavy strain on the upper portion of the pole. On his line they generally, instead of having them on one side of the pole, put one at the bottom, and so had a bottom bearing, which gave a much more substantial position to the pole, and then they generally put two cross-pieces of wood bolted through between the two poles, which made a stronger structure of it. In the pole shown in Fig. 2 there were no cross pieces at all. If either pole were to sink, all the strain was put on the cross-arms. He thought, perhaps, if Mr. Langdon looked at that system closely he would find that an alteration for the better might be made in that respect. With regard to staying poles, that was a most important matter, and one that he took up very strongly, because they had had such great difficulty in staying the poles properly, and he introduced a method of screw stay-rods to get out of the difficulty. It helped them to a great extent, but he found after some years' work that the heads of the bolts pulled through the blocks of work, although creosoted, through decay. He substituted then a stay plate, an iron plate, where the rod went through a hole with a flange each side to support it and to prevent it from turning. They never found any of them draw at all, and being made of cast iron they lasted very well underground. The iron arms he had not done very much with, but they did not always earth-wire the arms, as was done now. In connection with this staying question, Mr. Langdon also spoke of the snow falling on the wires. The stays were, of course, of very great assistance in the case of snowstorms. They had had lines for 30 or 40 miles broken down, and the poles dragged down in a shocking state. Snow attached itself to the wires and soon became covered with ice, presenting a considerable surface to the wind, which would break the wires and the poles would go down by the strain on the other side. The difficulty thus caused had been got over to some extent by staying the poles with the wires as well as laterally. If they stayed a pole first on the right side, and then another four or five poles away on the left side, that would limit the breaking down, for four or five poles, at any rate. With regard to insulation, Mr. Langdon stated that he had adopted on the Midland a system having one gauge of iron wire, No. 8, and one class of insulator. That was a good thing to do, and he thought most lines used one class of insulator now; but he did not see why, in open country, iron wire should not be used. Mr. Langdon seemed tohave a great preference for copper wire. There was no doubt that for lightness and conductivity it was an excellent wire to use, but on country branch lines, where they had a pure atmosphere, they did not know the end of iron wires. He (the speaker) knew of some which had been up for 35 years, and were still very good wires. It was much cheaper, as Mr. Langdon showed in the prices he had given. Copper wire, too, was very difficult to handle, and required great care on the part of the men who put it up. If they saw the elaborate instructions issued for the handling of copper wire they would be frightened to use it. With regard to the terminal insulator, that was a very good insulator indeed. The only fault of that as against the old shackle was that although it was a better insulator it was considerably more liable to pull over because of the strain at the top and the fixture at the bottom. With the shackle there was an equal strain at the top and bottom. This insulator made a very good system where they had to join wires together, as Mr. Langdon had shown, but he did not think it had any advantage over the shackle in sustaining the wire in case the earthenware or porcelain got broken. The leading-in cups shown in Fig. 6 were very excellent things, but they could not be considered a new introduction. Mr. Latimer Clark introduced them a good many years ago. Then with regard to the shortness of life of the iron wire, that depended entirely on the position where it was fixed. In South Wales, in the copper smoke, it lasted three years; in Birmingham, four or five years; and in London, six to seven years. The covering of the wire, West's compound, was a very excellent one indeed. They had found that if they warmed their wire and put it into boiling tar, and then sanded it with fine sand from the ironstone, it was coated with an enamel that was better than any other compound they had ever seen. There was some wire of that description put up between Wolverhampton and Worcester, and the iron beneath the enamel was as bright now as when it was put up 35 years ago, and was in excellent condition. It made a splendid preservative against atmospheric effects on the wire. But the worst of copper wire was that it was so liable to be damaged when being put by the draw-vice; it very often had to be painted over again and tarred over in order to cover those places up: otherwise the strongest link in the chain would become the weakest. The interlocking system had been adopted entirely on the Metropolitan Railway from one end to the other. They had a system also for shunting and protecting trains when on the wrong line or crossing from one line to the other. If a train on the up line had to cross to the down line, the up line was blocked; whilst it was crossing both lines were blocked; and when it was on the down line the up line was free and the down line was blocked. They used to have the iron tubing represented in Fig. 11, but they found that very often workmen with their pickaxes would break the tubes and damage the wires, and they found it better to put a thick oak or elm sheathing over them, so that the workmen would learn of their presence before doing any harm. The phonopore telephone was being used on a great many railways: this gave them the opportunity of speaking over the telegraphic wires whilst they were at work, and of holding a running conversation without any difficulty whatever. They could divide a long wire up into several short circuits by taking the connections from the telegraph wires into the administrative or other offices and making circuits as they wished, thereby telegraphing and telephoning at the same moment.

*Mr. CHARLES BRIGHT asked whether it was the custom to use gutta-percha for the underground wires instead of india-rubber, and why in using gutta-percha pains seemed to be taken to avoid moisture. He thought moisture was rather a good thing than otherwise. Was it the ozokerited tape that was damaged by the moisture or the gutta-percha?

*Mr. VON FISCHER TREUENFELD said telegraph engineers ought to be very much obliged to Mr. Langdon for bringing this subject forward. He was very pleased to see that at least one branch in telegraphy was not regarded as having reached finality, that of interlocking. He thought they would agree with him that not merely one, but a good many branches in telegraphy were still wanting in finality, and the general opinion which in recent years had prevailed was wrong, that the limit of the sphere of action of telegraphy had been reached, and that there was no further field for energy and intelligence to develop. They could suggest to the younger members of the electrical fraternity a splendid field for energy and development. With regard to the Paper, there were one or two points he would like to mention. The author referred to Mr. Alexander Siemens in connection with iron poles, and as Mr. Siemens was not present, he (the speaker) might, perhaps, be allowed to answer the questions in his stead. Iron telegraph poles had been very much and very successfully employed, especially in the Colonies, in consequence of their greater stability and greater ease of transport over long distances. But there was a strange fact, which iron manufacturers could probably better explain than telegraph engineers, and that was that iron telegraph poles of certain dimensions would not stand the breaking strain nowadays that they would 25 years ago. This fact had led to the necessity of devising new methods of construction which would give the poles greater stability, and Mr. Siemens had succeeded in doing this, and had taken out a patent for a pole of very simple arrangement. The lower part was of cast-iron tubing, and the upper portion of wrought-iron tubing. At first the top part was cemented to the upper 6in. or 9in. of the lower tube; but it was found that these poles broke at the joints, and Mr. Siemens had constructed a pole in which the upper tube was not fastened to the top 6in. or 9in. of the lower tube, but went right down inside to the bottom of the conical shaped bare tube. This gave a very solid pole, much stronger than the older form. If he might be allowed he would like to say a word or two against the employment of copper wire. He was fully aware of all the advantages of copper over iron wire. The electrical capacity and the consequent increase of speed in working, which amounted to something like 30 per cent., was enough to give the preference to copper over iron. He had in mind the very poor breaking strain of copper wire. The electrical resistance, as compared with that of iron, rose very nearly inversely as its price per ton, so that if they had to replace iron at 12½ ohms per mile by copper wire, they had to choose a No. 14 or No. 16 wire of 0·069 diameter. The breaking strain of the 7½ iron wire was about 1,300lb., but that of the 14 copper was only 290lb. If they adopted the rule that the tension of the span of the wire should not exceed a quarter of the actual breaking strain of that wire, there would be left a reserve breaking strain of 867lb. for the iron wire, and only 193lb. for the copper wire to oppose any extra tension or load such as would be caused by the accumulation of snow or the pressure of wind. It came to this, that telegraph lines erected of copper wire during a snowfall combined with wind were much more likely to succumb than those constructed of iron wire. He would ask the experience of Mr. Langdon with regard to the breaking down of copper wires in snowstorms.

*The PRESIDENT said it had long been an opprobrium to the Institution that they had no Papers from railway telegraph engineers, but Mr. Langdon had certainly removed that opprobrium, and he believed at great inconvenience to himself.

*Mr. LANGDON, replying to the points raised in the discussion, said no doubt interlocking had progressed during the last three or four years to a considerable extent on the lines mentioned, but particularly on the South-Western and Great Eastern. There was no doubt this interlocking was a most desirable thing; but it was to be regretted that in undertaking this matter the companies should not have dealt with it in a more final manner. As he stated in the Paper, it was the first vehicle which gave relief to the block section. A train entering a section put on the starting signal automatically, and the block signals were put on

Digitized by Google

by hand; those block signals controlled the mechanical signals, and they remained locked until the train passed out of the section. If a train happened to be divided, the second portion remained in the section, and if one vehicle passed over the redress point that enabled the signalman to clear the train and another train might then come in and cause a serious accident. Therefore the present system had no finality about it, and it would be well for the railways companies to consider the matter further. Complete safety was only to be attained by attaching to the last vehicle of the train something which should give the signal "train out of section." If the train divided that vehicle would remain on the line and the signal would not be cleared. Mr. Wyles had mentioned that electricity was rendering considerable aid in what he termed the mechanical departments, that is to say, that it had taken the place of mechanical appliances; Mr. Treuenfeld also indicated that there was a larger field. That was undoubtedly so, and it was only necessary for railway engineers to associate themselves with other branches of the service to find out those places where it could be applied and make use of it. Mr. Goldstone had corrected him with reference to duplex working on the South-Western Railway. He was not aware that he had made the mistake, but if he found it was the case, he would correct it. Mr. Spagnoletti took exception to the "H" pole system; he had probably forgotten the diagonal piece at the bottom, the object of which was to prevent that scissors motion which Mr. Spagnoletti thought would arise. There was nothing, of course, to prevent one pole sinking more than another. That was why in planting the second pole he allowed it to stand for a time before trying to consolidate the structure by putting on the cross arms. The proof of the pudding was in the eating, and the point was that they had erected some hundred miles of those poles and had not found one sink more than the other. He did not think he was entitled to any credit in the matter, because he believed it had been done by other engineers before, although perhaps not to any great extent. Then Mr. Spagnoletti pointed out that the stay rods sometimes pulled out. He never knew them do so unless the blocks were rotten. In all stay rods there was a plate at the bottom of the block, and the head of the rod banked upon that plate; that ought to prevent it from going through unless it was very rotten.—[Mr. SPAGNOLETTI: I referred to rotten ones].—If they were creosoted they ought not to rot. With reference to lateral staying, he had not mentioned it, but it was a practice pursued by him for many years. It had been the case that they had had a serious breakdown, and the wires ran back. The way to prevent that was to have lateral stays at every tenth pole where the poles exceeded 20. Mr. Spagnoletti also mentioned his experience that iron wire lasted 35 years. He could only congratulate Mr. Spagnoletti on having such a locality; he wished he had such. Either the districts where his Company's lines ran were more smoky or their wire was very inferior. It had been said that there was a difficulty in the handling of copper wire. He had not experienced it; the men under his direction found no difficulty. They had to be careful not to pull it up too tight, but they had their tension tables, which showed them the amount of strain to put on the wire in putting it up; they complied with that, and there was no difficulty whatever. There was no question that the shackle had a much more direct influence upon a wire than a terminal insulator. There was not the leverage about it, the strain came direct in the loop, but at the same time it was an inferior insulator. Mr. Spagnoletti might also be quite right with reference to leading-in cups, although he (the speaker) did not remember their being in use at the time mentioned. As to wire being steeped in boiling tar, it occurred to him the value of tar as a protective resided mainly in the oil it possessed, and when that oil evaporated under the influence of the sun there was nothing but the sediment left, which would be a very poor protection for the wire. That was his experience. At the same time he must admit he had not heated wire and steeped it in boiling tar. With respect to the phonopore, his Company had enjoyed its use to a limited extent, and if those who had the phonopore in their hands could only arrange it in such a manner that it would dispense with the induction they got from it it would be an excellent instrument. The induction interfered with their telephones, and they get nothing but complaints. Mr. Charles Bright asked why gutta-percha was used for underground work rather than india rubber. Gutta-percha had been used for a good many years. India-rubber, he had no doubt, was equally good. It became more plastic when exposed to the air. If they could keep gutta-percha always in the water undoubtedly that would be the best thing to do, but that was an impossibility, and if they had it sometimes dry and sometimes wet it soon became porous. Mr. Treuenfeld called attention to iron poles. Iron poles had been tried, to a certain extent, on railways, but they were not large enough or strong enough for their purposes unless they went to great expense—such an expense as would be wasteful in comparison with creosoted poles. Then Mr. Treuenfold objected to copper wire, as compared with iron wire, and he had strengthened his argument somewhat by reference to the accumulation of snow on wires. It was very strange, but he found very little difference between the amount of snow gathered by the iron wire and that gathered by the copper wire, although one might be much larger than the other. At all events, the experience they had was that copper wire stood just as well as the iron.

## THE EVOLUTION OF THE STORAGE BATTERY.*

BY MAURICE BARNETT.

The history of the advances which have been made in producing electricity by chemical means is traced from the time of Gauterot in 1801, to 1859, when Planté made a systematic examination of polarisation effects with the view to their utilisation, and brought out his well-known form of battery, zinc, iron, and even copper, which on account of the energy they develop during chemical action, would be even more efficient than lead for the purpose of battery construction, but are objectionable on account of the solubility of their salts. Lead furnishes salts which are practically insoluble in the electrolyte. The influence which this insolubility exerts in diminishing local action is apparent on consideration. The peroxide and the metallic lead of the positive and negative plates, respectively, are both converted into sulphate during discharge. The same reaction takes place as the result of local action. Now as this sulphate forms, it gradually encloses the remaining active-material, and protects it from further loss. Again, the fundamental principle of the storage battery is the possibility of reversing the physical and chemical changes which take place during each discharge. With soluble electrodes, the difficulty that lies in the way of the redeposition of the metal in an efficient form seems almost insuperable. Up to the present day, effort after effort has been made to accomplish this, but without anything like a satisfactory result. The consequence is that recourse has been had to electrodes which are either insoluble, or which, like lead, form salts insoluble in the electrolyte. At the present time lead is the only metal used to any extent in the manufacture of storage batteries. Zinc and copper have been used with lead in what are known as the Reynier and the Sutton cells, while zinc has been used with copper in the Thomson-Houston and the Waddell-Entz cells. This departure from the lead type of battery has not been attended with success. Lead seems to be the only metal of which it can be said that it is easy to reproduce both the physical and chemical changes which take place in the electrodes during discharge, and this reversal may be repeated almost indefinitely without the plate showing much deterioration. Two other properties of lead adapt it for use in the construction of storage batteries—first, the conductivity of its peroxide, and, secondly, the high E.M.F. furnished by a lead and lead peroxide couple in dilute sulphuric acid.

Between 1859, when Planté began his experiments, and 1880, when Faure invented the pasted battery, the dynamo-electric machine had been perfected, and offered the means for the cheap production of currents of great density and high E.M.F. This circumstance put the storage battery on a different footing, and held out a promise of its future utility. Faure's invention had for its object the reduction of the time and cost of the Planté process of formation, and consisted in coating the plates with red lead and litharge respectively. Scarcely had the Faure plate been brought out than accumulators were put to a variety of uses, and as far back as 1883 an electric car furnished with a Siemens dynamo used as a motor, and about 4,000lb. of batteries, was run at Kew Bridge.

The storage battery was put upon the market in a crude and undeveloped form before it had been sufficiently studied by the chemist and the physicist, and improved by the manufacturer. In addition to this, it was applied to a variety of purposes for which in its early form it was notoriously unfit. Failure resulted, and the prejudice thus created still exists, although secondary batteries as now manufactured give satisfaction. So great an improvement was the Faure battery supposed to be over that of Planté, that between 1880 and 1890 it was thought that no commercial storage battery could be made that was not of the pasted type. Recently the Planté type has again come into favour, together with an improved form of battery known as the chloride accumulator. These are all lead batteries. Planté batteries are made in diverse forms. In the first place, there are the solid plates with striated surfaces. Then there are the various forms of laminated plates, where the greater part of the body of the plate consists of ribbons of lead. Then again there are other forms where porosity is given to the lead by kneading it hot with some porous material, which may afterwards be dissolved out. The objects aimed at by increasing the surface of the lead per pound of material, are: first, to facilitate the forming process (it is easy to see that the more surface there is, the more lead will be exposed to the electrolyte, and the more quickly will electrolytic action accomplish the requisite formation); second, to increase the capacity of the plates, *i.e.*, the ampere-hour output per pound of the elements; third, to permit changes of volume to take place in the active material without prejudice to the life and efficiency of the cells. The plates are sometimes formed by the Planté method, and sometimes by an electro-chemical treatment which quickens the process. The characteristics of the Planté type of battery are: capability of giving heavy discharges without sustaining

Digitized by Google

injury, minimum local action, and general freedom from the irregularities due to local action. In the Faure type of cell, a paste of minium or litharge respectively is applied to the plates, which may be perforated or solid, and their formation is then completed by electrolysis. When these cells go into service local action occurs between the active material and its support, which, amongst other things, leads to the loss of the charge of the battery and to the formation of lead sulphate, which weakens the contact between the paste and the grid. Expansion takes place in every direction in the active material, which is an ordinary mechanical mixture, with the result that it falls away, causing short circuits between adjacent plates and deteriorating the cell. The Tudor positive is a modern form of pasted plate, which requires special mention. The plate is heavy and thick, and provided with grooves or channels to support the active material. A paste of red lead is applied to both sides of the plate, which is then formed electrolytically. This form of battery is specially adapted to central station work, as it is capable of yielding the whole of its discharge in one or two hours, and is employed in 80 per cent. of the central stations in Prussia and Austria. The lead chloride battery takes its name from the fact that its active material is prepared from lead chloride rather than from metallic lead, as in the Planté type. Lead chloride is cast into small pastilles, with bevelled edges. These, spaced in moulds, have antimonial lead cast around them under pressure. The resulting plates, alternating with sheets of zinc, with which they are in dead short-circuit, are then placed in a solution of chloride of zinc, and allowed to remain until the zinc chloride has been dissolved out and the lead brought to a metallic state. The active material of these plates is porous, and of a fine crystalline structure. The positives are formed electrolytically. The claims made for this battery are: (1) Good contact between the active material and support, owing to the bevelled edges of the original chloride tablets, and the lead forced around them under pressure; (2) that the crystalline formation allows of changes of volume without undue strain being set up; (3) that the cohesion of a crystalline mass is always greater than that of a mechanical mixture; (4) that the porous condition of the active material secures large capacity per pound of elements; (5) that the porous condition facilitates formation. These claims appear to be substantiated in practice. Choride batteries are Planté cells, but differ from this type in that the lead which is to furnish the active material is prepared separately from the rest of the plate. Choride negatives are said to be the best which have yet been produced, and are largely used with other forms of positives.

## DISCUSSION.

Mr. C. J. REED stated that there were some points raised in this interesting and instructive Paper on which he was unable to agree with the author. The reduction of lead sulphate was stated by him, as it was generally stated by others, to be affected by the action of nascent hydrogen. In other words, it is held that the electric current first decomposes the solution, liberating hydrogen and oxygen; that the hydrogen reacts on the lead sulphate, producing metallic lead and sulphuric acid, while the oxygen at the positive plate acts upon the lead sulphate and water, producing lead peroxide and sulphuric acid. There is no evidence to substantiate the theory of this double reaction, and we have every reason to believe that the charging of the accumulator results directly in the electrolysis of lead sulphate on both plates, as stated by Leibenow in the *Zeit. f. Electrochem.*, January 5, 1895. If oxygen and hydrogen are produced as the first step by the current, we have no way of knowing it, since the gases are not evolved. Pure, chemically precipitated $PbSO_4$ is easily changed to $PbO_2$ and Pb by the electric current, references to the contrary notwithstanding. If a paste of pure $PbSO_4$ and pure water be placed between lead or platinum electrodes, and a current passed through the mixture, the paste is rapidly converted into $PbO_2$ and Pb. In this case, at least, there can be no decomposition of the $H_2O$ at the beginning, since pure water is not an electrolyte, and no $H_2SO_4$ is present. The formation heat of PbO is 55,350 calories, corresponding to an E.M.F. of 1·19 volts, and that of $H_2O$ is not less than 68,360, corresponding to 1·47 volts. The formation heat of $H_2SO_4$ (assuming $H_2$, $O = 68,360$ and $SO_3$, $H_2O = 21,310$) is 89,680, and that of dilute sulphuric acid 107,530 calories, corresponding respectively to 1·93 and 2·22 volts, whilst that of $PbSO_4$ is only 75,552 calories (not 145,130 as given by Mr. Barnett) corresponding to 1·63 volts. It is known also that $H_2O$ is not an electrolyte and could not be decomposed. The liberation of hydrogen, therefore, will require greater E.M.F. than that of lead, and there is no more reason to suppose that the reduction of lead sulphate is effected by nascent hydrogen than there is to suppose that the latter effects the deposition of copper in electroplating. It is merely a question of whether lead or hydrogen has the greater heat of combination per electro-chemical equivalent. This explains the absence of gassing on the commencement of charge, as the current is all employed in the decomposition of lead sulphate on both plates according to the equation—

Pos. plate. Neg. plate.

$$PbSO_4 + 2H_2O + PbSO_4 = Pb + PbO_2 + 2H_2SO_4.$$

As the lead sulphate is used up during charge the current begins to decompose the solution with the evolution of free oxygen and hydrogen, and this accounts for the higher E.M.F. required towards the end of the charge. The only products of discharge are, as stated by Messrs. Gladstone and Tribe, $H_2SO_4$ and $PbSO_4$, the latter mixed in varying proportions with $PbO_2$ on the one plate and with Pb on the other. The only lead products of the charging process that have ever been found are lead and lead peroxide. Under these circumstances there is formed on the solution some $H_2O_2$, $O_3$ and $H_2S_2O_8$, but no lead persulphate or any other compound of lead except the peroxide. If any lead persulphate were formed incidentally in charging, it would immediately be dissolved in the solution, and could no longer be considered a part of the active material of the electrode. Its gradual spontaneous decomposition would cause a white precipitate of lead sulphate in the bottom of the cell. But to consider such a product as the normal result of charging an accumulator, or as an intermediate step in the formation of lead peroxide is out of the question. If such were the case the positive plate would go into solution the first time it was charged. The only lead persulphate known to exist is so highly soluble that it can be brought into the solid state only by evaporating its solution in vacuo. The second question raised in the Paper with which Mr. Reed cannot agree is the statement that an insoluble active material is necessary or desirable in an accumulator to prevent local action. Any insoluble coating that prevents local action must also interfere with the normal action of charge and discharge.

Mr. BARNETT: The electrolytic decomposition of $PbSO_4$ is more difficult than Mr. Reed supposes, and he will find it hard to prove that it is effected without the agency of hydrogen. Lord Kelvin and Dr. Lodge objected originally to the lead sulphate theory of the action of accumulators because of the impossibility of reducing lead sulphate, and even Gladstone and Tribe showed that it was only partially reduced after days of electrolytic action. There is nothing in the nature of lead persulphate to preclude it being an intermediary in the conversion of $PbSO_4$ into $PbO_2$. Admitting its solubility, it must be remembered that it is an endothermic compound, and is decomposed as soon as formed with the production of $PbO_2$ and regeneration of $H_2SO_4$. It could not, therefore, disperse through the electrolyte. Dr. H. Marshall, in Vol. LIX. of the *Journal* of the Chemical Society, London, describes the action of PbO on ammonium persulphate, which gives rise to the formation of water, lead persulphate, and ammonia according to the following equation:—

$$(NH_4)_2(SO_4)_2 + PbO = Pb(SO_4)_2 + H_2O + 2(NH_3).$$

This lead persulphate in presence of water yields lead peroxide and sulphuric acid as follows:—

$$Pb(SO_4)_2 + 2H_2O = PbO_2 + 2H_2SO_4,$$

which explains why no soluble persulphate of lead is found in the electrolyte, for it has been decomposed. Gore, on p. 40 of his "Electrolytic Separation of Metals," gives the heat of formation of $PbSO_4$ on Thomson's authority as 145,130 c.g. calories, and the chemical equation of the discharge of the lead cell with the corresponding heats of formation of the substances produced shows that there is no ground for doubting the accuracy of the above figures. The electrolytic equation of the action of lead accumulators may be written as follows:—

$(2PbSO_4) + (2H_2O) - 2H_2SO_4 19H_2O)$
290,260 + 136,720 − 277,280 app.
$+[\text{Electrolyte} + 2\,19H_2O + H_2O)] - PbO_2 = 90,970$ c.g. calories.
+3,520 − 62,300

Apply Sir W. Thomson's rule, and we get an E.M.F. of 2 volts, which agrees with the results attained in practice. The E.M.F. required for charging is sufficient to decompose the electrolyte and to break up $PbSO_4$, and when that compound is broken up the $SO_4$ is not transferred to the positive plate, but combines at once with the hydrogen to form hydrogen sulphate. There are endothermic compounds (or those which *absorb* heat when their constituents unite), as well as exothermic compounds, which give out heat when their constituents unite. It makes no difference, therefore, whether the heat of formation of $H_2SO_4$ is greater or less than that of $PbSO_4$. In 1878 Berthelot discovered persulphuric acid, and showed that it was the primary product at the positive electrode when dilute $H_2SO_4$ was electrolised, and yet, according to Mr. Reed, such a compound could not be formed because it absorbs heat. Mr. Reed knows that in charging an accumulator there is consumed nearly 20 per cent. of energy in excess of what is needed to overcome electrical resistance. Does it not occur to him that part of this is used in effecting endothermic combinations? If the E.M.F. of a charging current were capable of decomposing $PbSO_4$ *without decomposing the electrolyte*, then we could have the reaction given by Mr. Reed:—

$$PbSO_4 + 2H_2O + PbSO = PbO_2 + Pb + 2H_2SO_4.$$

But, as a matter of fact, the charging current is always capable of decomposing the electrolyte, therefore the hydrogen formed at the negative plate must combine with the $SO_4$ simultaneously liberated there. If we reject this view, we must consider that when the electro-negative ($SO_4$) of the $PbSO_4$ is attracted to the positive pole, the electro-positive (Pb) is attracted to the negative pole, with the result that under continuous charging the negative plate ought to have deposited on it an amount of lead which is only limited by the existence of the positive plate. This view is absurd, but it is the logical outcome of the hypothesis that the independent electrolysis of $PbSO_4$ is concerned with the charging reactions of the lead cell. Lastly, as regards the necessity or desirability of having insoluble active material as a preventive of local action, it would obviously be preferable to prevent it by other means, but can this be done at present? Soluble electrodes are objected to chiefly on account of the difficulty in reversing the physical and the chemical changes taking place in the cell. Though lead is not a good electrode, especially for the negative plate, we do not find any cells in successful operation where soluble electrodes are employed. Of the numerous modifications of the "Sutton" type of accumulator, consisting of a lead peroxide-copper couple in an electrolyte of copper sulphate; of the "Reynier" type, consisting of a lead peroxide-zinc couple in an electrolyte of zinc sulphate; of the "Thomson-Houston" type, which is a reverse form of the Daniell cell; and lastly, the "Waddell-Entz" type, consisting of porous copper oxide and metallic zinc in an electrolyte of potassium zincate—can Mr. Reed point to any of these in successful operation to-day?

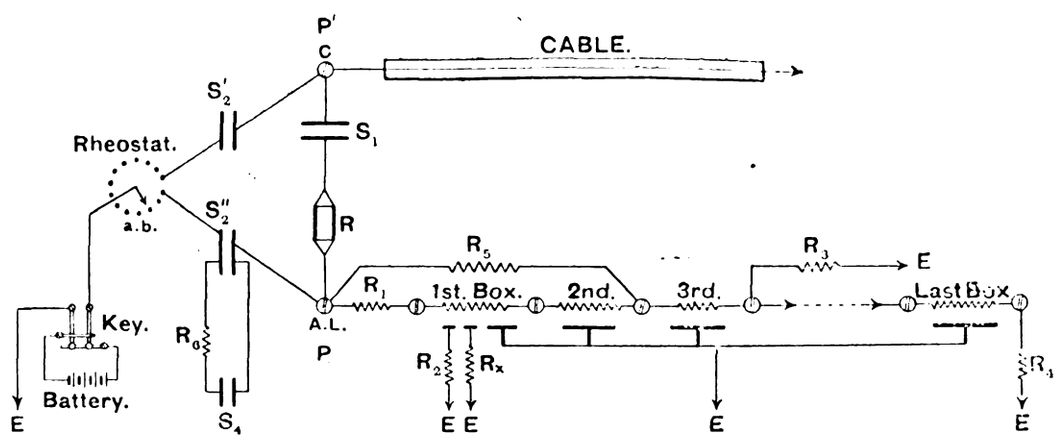
## "DUPLEX" ON SUBMARINE CABLES.

In a pamphlet recently copyrighted and issued privately to the working staffs of several of the leading cable companies, a series of hints are given to operators on "Duplex" from which we extract the following :—

In the accompanying figure, *a*, *b* are the rheostat coils, commonly called the "quarter ohm rheostat," because its resistance can be varied by a quarter of an ohm at a time. Its function is to introduce a variable resistance between the battery and the condenser blocks $S_2'$, $S_2''$, and thus to regulate the rate of charge into the latter with regard to each other. This rheostat is also provided with one fixed coil, marked 10 ohms, and with a shunt commutator, connected. $S_2'$, $S_2''$ are the bridge condensers, which are substituted for resistances when balancing long cables. $S_1$ are the receiving condensers. $S_4$ is a sub-divided condenser, facilitating the introduction of different capacities at $S_2''$. This condenser is subdivided to hundredths of a microfarad. $R_1$ is a resistance provided with a subdivided ohm adjustment for adding to the resistance of the artificial line. This has the effect of raising the potential at P with respect to $P_1$. $R_2$, $R_x$, are resistances inserted between the earth plates of the artificial line and the earth, $R_2$, or $R_x$, according to the amount of variation of temperature of the A.L and the underground wire to the cable which may take place during the 24 hours.

It is important to remember that resistances or condensers inserted in the "cross circuit," that is to say, between C and A L, will not affect the duplex balance—assuming always that their insulation is good—but they *will* affect the received signals. Increasing $S_1$ will augment the range of the signals, but if too great a capacity is employed the signals become straggly and of bad shape, and if, on the other hand, too small a capacity is used, they are rendered small and unsafe. As the ratio of the resistance to the capacity of the "artificial line" is usually somewhat higher than that of the cable, the tendency will be for the potential to rise more quickly on the artificialline side; consequently, it is usually necessary to make the condenser block $S_2''$ on the artificial line side somewhat smaller than that on the cable side. The effect of adjustments at the beginning or "home end" of the artificial line is much more marked than that caused by adjustments nearer the further end. For instance, any small alteration of the quarter ohm rheostat, of $S_1$, of $R_1$ and of $R_2$ and $R_x$ (if the latter be interpolated between a large number of condenser terminals and the earth, or if between a fewer number of terminals and the earth at the beginning of the artificial line) will have a much greater effect on the balance than comparatively large changes



to retard the rate of charge into the plates. This has *practically* the effect of decreasing the capacity of the plates so adjusted. $R_3$ is a "leak" from any line terminal of the A. L. to earth. A resistance of, say, 3,000 to 10,000 ohms is usually employed, but sometimes two leaks are found to be advantageous, one of a high resistance and one of a low, the former generally nearer the home end. These leaks are useful in eliminating the wave in a duplex balance. A resistance, $R_5$, is inserted between the end of the artificial line and earth when required, usually from 1,000 to 5,000 ohms. $R_3$ is a resistance placed as a shunt between any two of the artificial line terminals (line side). A resistance, $R_6$, is inserted in the subdivided condenser ($S_4$) circuit to retard the rate of charge into the condenser. Sometimes this adjustment is found useful in eliminating a "jar" in a duplex balance, but it is not frequently employed.

For cables exceeding 300 miles in length a balance will be found as follows:—Having substituted condensers $S_2'$ and $S_2''$, and a finely-subdivided condenser $S_4$ connected up with the latter for purposes of adjustment in the place of the bridge arms used on shorter cables, commence with the adjustable condenser $S_4$ and the resistance $R_1$ at nil, and send a rather rapid succession of "dots" by means of the key, and turn the knob backwards and forwards until the best balance procurable is obtained. If a satisfactory result is not so obtained, insert 0·05 microfarad in $S_4$, increase or diminish it by 0·01 or 0·02 microfarad at a time, after each alteration obtaining the best balance possible by means of the rheostat. Should the last adjustment not be effectual make the resistance of $R_1$ 5 ohms, and increase or diminish it by 1 ohm at a time, after each alteration obtaining the best balance possible by means of the rheostat, in the same manner as when adjusting the subdivided condenser $S_4$, always proceeding in the direction of improvement. When getting the balance near, alter $R_1$ by smaller amounts, say halves or tenths of ohms, as the case may require. Should there still remain a "jar" of the mirror, or blurred line on the recorder slip while signalling on one key, which is unaffected by any variation of the condenser $S_4$ and the resistance $R_1$, then insert the resistance box $R_2$ between the first capacity or earth terminal of the first box of the A.L. and the earth. From day to day it will be found necessary to alter the rheostat and the subdivided condenser $S_4$, and perhaps the resistances $R_1$, in $R_3$, $R_1$, or $R_5$. A spare recorder is sometimes inserted between the end of the artificial line and earth, in the place of $R_5$, or in conjunction with $R_1$, or in one of the "leak" circuits, where its resistance can be made to form part of the "leak," and in these positions it affords a ready means of recording the sending signals passing to the receiving station.

## ON VISCOUS DIELECTRIC HYSTERESIS.*

BY RICCARDO ARNÒ.

The phenomenon which I discovered of the rotation of a dielectric cylinder in a rotating electric field †, and the results of my experiments on the dissipation of energy in the dielectric placed in such a field ‡, demonstrate the existence of a lag with which the polarisation of the dielectric follows the rotation of the field itself.

Two kinds of lag may produce the dissipation of energy demonstrated: either a lag in the variation of the dielectric constant by which this would have smaller values for a field of increasing than for one of diminishing intensity; or a time retardation between the instant of application of the electric force and the instant at which the dielectric has attained its corresponding polarisation.

To this second species of lag, which may be described as viscous dielectric hysteresis, part at least of the dissipation of energy in dielectrics in an alternating electric field may be due. This follows essentially—

(1) From Northrup's experiments, § which show that the value of the specific inductive capacity of a dielectric under the influence of a cyclically varying electric field, depends upon the rate of variation of the field itself.

* *Rendiconti dei Lincei*, Vol. V., 5A, pp. 262-264.

† *Rendiconti*, Oct. 16, 1892. See *The Electrician*, Vol. XXX., p. 516.

‡ *Rendiconti*, April 30, and Nov. 12, 1893, March 18, June 17, and Nov. 18, 1894. See also *The Electrician*, Vol. XXXI., p. 201; XXXII., p. 222; XXXIII., p. 210; XXXIV., p. 327.

§ *Phil. Mag.*, January, 1895.

Digitized by Google

(2) From the experiments of Janet*, and of Porter and Morris,† on condensers subjected to rapid and to slow electric oscillations for a given value of the difference of potential between the armatures. In the first case, the charge is smaller when the difference of potential is increasing than when it is diminishing; in the second case it is constant.

(3) From Eisler's‡ experiments, which bring out the influence of the frequency of a given alternating difference of potential on the loss of energy, and show that this loss increases at first with the frequency, and then reaches a maximum and decreases again.

The experiments of which I give the results here were undertaken in order to test whether the dissipation of energy in a rotating field must also, like that in an alternating field, be partly attributed to viscous dielectric hysteresis. The effect of viscous hysteresis is, for a rotating field, a function of the velocity of rotation of the field. Hence it will suffice if we maintain a field of uniform strength and vary its velocity of rotation.

As before, I used two alternating fields of equal intensity perpendicular to each other, and having a difference of phase of 90 deg., obtained from a single alternating current. The duration of a single rotation is then equal to the period of the alternating current. Hence, in order to vary the speed of rotation, it was only necessary to vary the frequency of the original current, while maintaining the two fields at the same strength.

In the following table are shown the results of the experiments, performed with the apparatus previously described, corresponding to two values (0·083 and 1·818 C.G.S. units) of the electrostatic induction B, using a hollow cylinder of paraffined cardboard weighing 2·011 grammes, and 26mm. high, 30mm. in external diameter, and 1mm. thick. In the second column are given the frequencies $n$ of the current, and in the third the deflection $d$ of the cylinder and mirror as read with the telescope :—

| No. | | $n$. | $d$. |
|---|---|---|---|
| I. B = 0·083 | 1 | 44 | 5·5 |
| | 2 | 22 | 9·5 |
| | 3 | 11 | 13·5 |
| II. B = 1·318 | 4 | 44 | 59 |
| | 5 | 22 | 87 |
| | 2 | 11 | 129 |

The reading $d$, which is proportional to the work in ergs performed performed per cycle by the deflecting electric forces, must be referred to two different degrees of sensitiveness of the apparatus, changed according to the induction B.

These results show that the energy dissipated in each cycle in the dielectric cylinder varies with the rate of rotation of the field. It therefore appears that the dissipation of energy, or part of it, is the effect of viscous hysteresis in the dielectric examined.

## PHYSICAL SOCIETY.

At an ordinary meeting of the Physical Society, held on May 8th, 1896, Capt. Abney (president) in the chair, Messrs. FRITH and RODGERS read a Paper on

### "The True Resistance of the Electric Arc."

It was pointed out by Prof. Ayrton at the British Association meeting at Ipswich that if the "true resistance" of an arc is defined as the ratio of a small increase of the P.D. between the carbons to the corresponding change in the current, then it follows that this "true resistance" must be a negative quantity.

In order to measure the "true resistance" without appreciably altering the form of the carbons, &c., the authors superpose a small alternating current on the main continuous current. The arc lamp employed was adjusted by hand, and the arc length was measured by projecting an image of the arc by means of a lens. The main (continuous) current and P.D. were measured by a Weston ammeter and voltmeter, while the auxiliary alternating current was measured by means of an air transformer and an electrostatic voltmeter.

The authors find that between the limits employed the magnitude of the alternating current did not influence the results obtained for the resistance of the arc. The frequency, so long as it lies between the limits 250–7 complete alternations per second, and the wave form do not influence the resistance, since the same results were obtained with a Pyke and Harris alternator, a Ferranti alternator, a Gramme alternator and a Mordey transformer.

For each make of carbon examined four combinations were used : + cored, – cored ; + cored, – solid ; + solid, – cored ; + solid, – solid. The general characteristic of the curves obtained is that for the + solid – solid combination the "true resistance" is always negative, while for + cored – cored it is always positive, the other curves being between these two extremes, those which have the + carbon solid always being more negative than those which have the + carbon cored. In the case of the curves showing, for solid carbons, the relation between the resistance of the arc and the P.D. between the carbons, the current being constant (10 amperes), a minimum (maximum negative) value for the resistance occurs at about 55 volts. With combinations having a cored positive this minimum becomes more strongly marked and occurs at a lower voltage. The authors find that for cored carbons the position of this minimum is closely connected with the presence or absence of the dark space in the arc. For points on the curve to the right of the minimum point the dark space is absent, while for points to the left of the minimum the dark space is always present.

It was found that the effect of using as the + carbon a Carré carbon in which the core had been bored out, was to obtain a curve closely resembling that obtained when both carbons were solid. On filling this hollow carbon with plaster of Paris or kaolin, the resistance of the arc became positive.

The above experiments were made with the + carbon uppermost ; other experiments made with the arc inverted showed that with solid carbons the resistance is not appreciably altered by inverting the arc. With cored carbons, however, the resistance as well as the physical character of the arc is altered, for on inversion the dark space disappears and the resistance considerably diminishes. If, however, the conditions under which the arc is burning are such that the dark space is absent, then inverting the arc does not alter the resistance.

Attempts were made to measure the "true resistance" of a direct-current hissing arc, but it was found that even with the alternator at rest there was a large deflection of the electrometer, showing that the current through a hissing arc was oscillatory.

In order to elucidate the marked difference between their results for cored carbons and those deduced from Mrs. Ayrton's curves, the authors have made a series of measurements at low frequencies. They find that there is a critical frequency, above which the resistance has a positive value, which is independent of the frequency, and below which it has a negative value, this critical frequency being between 75 and 0. In order to investigate the sign of the resistance at low frequencies the vibrations of the needles of the ammeter and voltmeter were made use of. By an arrangement of mirrors, the needles and scales of both instruments could be observed simultaneously. In this way, it would be seen whether the two needles were, at any instant, vibrating in the same or in opposite directions. If the needles vibrate in the same phase, *i.e.*, if an increase of P.D. is accompanied by an increase of current, then the resistance must be positive ; while if they are vibrating out of phase, *i.e.*, if an increase of P.D. is accompanied by a decrease in current, then the resistance is negative.

An attempt to run the arc off a continuous-current dynamo failed, since even with the alternator at rest the electrometer showed a large deflection, evidently due to the oscillation of the current owing to the commutator of the dynamo having a finite number of segments.

Prof. A. GRAY doubted whether it was right to give the name "true resistance" of the arc to the slope of the curve connecting the potential difference (V) and the current (A). The authors' method of deducing $\frac{\delta V}{\delta A}$ was only true if the curve was a straight line, while in the case of the arc E and $\alpha$ may both vary with the current.

Mrs. AYRTON said that with reference to the question of the existence of a back E.M.F. the evidence tended to show that it did not exist. By using an exploring carbon no constant back E.M.F. would be found.

Prof. AYRTON said that considering the arc as consisting of a back E.M.F. and a resistance, it was necessary to separate these two. Simply obtaining one value of the P.D. and the current was of no assistance in solving this question, but a series of values had to be taken. By taking the change in P.D. and current sufficiently small the curve over the range considered was practically straight. It was curious to note that as long as observers obtained a positive value for the resistance of the arc no fault was found with the method, but that now a negative value was found the accuracy of this method was questioned. If a back E.M.F. does really exist, then it follows that the arc must have a negative resistance. Mr. Frith has shown why some people have got positive and some negative values for the resistance of the arc and also that with an alternating current you may get either one or the other.

Mr. CARTER asked if the fact that the arc had a negative resistance did not imply a back E.M.F., in order that the arc might be stable ? If so, was a negative resistance such an absurdity ?

Mr. CAMPBELL said he was very pleased to see that the authors had applied a method which he (Mr. Campbell) had suggested for measuring pulsating currents. If a pulsating current such as could be obtained by means of a make and break is passed through a thermopile you would get a back E.M.F., while if an alternating current were employed you would not.

Mr. FRITH, in his reply, said that he had defined the "true resistance" as $\frac{\delta V}{\delta A}$. Mrs. Ayrton has shown that an arc will not run unless a certain resistance is placed in series with it, this resistance must be numerically equal to the negative resistance of the arc itself.

Prof. AYRTON said Mr. Frith's remarks as to the cause of the want of stability of an arc without outside resistance were most suggestive.

The CHAIRMAN (Capt. Abney) said he did not like the expression potential difference. He suggested the employment of photography to facilitate the accurate registration of the instrument readings.

**The further discussion on the Paper was adjourned to the next meeting on May 22nd.**

## LONDON COUNTY COUNCIL.

At the weekly meeting of the London County Council held on Tuesday, the Finance Committee reported upon the application of the Vestry of St. Pancras for a loan of £75,000 for electric lighting purposes and a refuse destructor at the King's-road station. In July, 1896, the Council agreed to lend £30,000 for electric lighting purposes, and £26,100 for the dust destructor, and the Committee now recommended that the application for a further loan of £18,900 towards defraying the cost of carrying out an electric lighting installation be granted to the extent of £15,300, and further that the Vestry be notified that, as they had elected to spread the whole of the initial cost of the electric lighting installation over 42 years, the Council would decline to give its sanction to the raising of any loan to replace plant and machinery which might be necessary during the currency of the loan, and would expect all renewals to be provided from a sinking fund or from maintenance account.—The recommendation was agreed to.

The Bridges Committee submitted a scheme for a new foot tunnel under the Thames to connect Greenwich and Millwall. The proposed tunnel would be lighted by electricity. It was also proposed to lay pipes in the concrete below the footway for telephone wires, &c. With regard to maintenance, the Committee proposed that electricity for lighting should be used, and it would also be used for working the ventilating and pumping machinery. The cost of the installation and upkeep of an independent plant would be very expensive, and they had received a proposal from the London Electric Supply Corporation to lay a cable from the nearest point of the Company's mains to the south end of the subway for about £1,000, which would in the first instance be paid for by the Council, and to supply the current at the rate of 4d. per unit. The Committee had reason to believe that the Electric Supply Corporation would be willing to enter into an agreement to return the £1,000 within five years, or in a shorter time if it were found that private consumers in any number took current from the main. The Committee considered the proposal to be satisfactory, and to show a great economy over the results which would be obtained by putting down a special installation.—As the recommendation involved an expenditure of over £5,000 the report stood postponed till the next sitting.

The Fire Brigade Committee reported that in connection with the establishment of the Kingsland and Shoreditch Fire Stations estimates had been obtained from the Post Office (*a*) For Kingsland, 10 Stuart's fire alarms (four to have telephones attached), 2 portable telephones, and a 6-hole switch, £125, less £54. 5s. in respect of fire alarms now connected with other stations; (*b*) for Shoreditch, 11 Stuart's fire alarms (three to have telephones attached), 2 portable telephones, and a 6-hole switch, £124. 15s., less £63 in respect of fire alarms connected with other stations; (*c*) for Hackney, 5 Saunders and Brown's fire alarms (3 to have telephones affixed), and a 4-hole switch, £57. 15s., less £19. 10s. in respect of alarms connected with other stations; (*d*) for Bishopsgate, 1 Saunders and Brown's fire alarm, £6. 15s.—It was recommended that these arrangements be sanctioned, and this was agreed to.

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May 1, 1896.*

**The Electrical Exhibition.**—At the present time all interest is centred in the Electrical Exhibition which opens in this city next week, and will continue during the month of May. It is evident that the show will greatly surpass the most sanguine expectations of its projectors, and it will be in many respects the most unique and extensive electrical exhibition ever held, not excepting even the World's Fair display. Besides the industrial features of the Exhibition, it will be notable for the exhibits of historical and experimental apparatus used in research in every department of electrical science. Among the historical and special exhibits may be noted that of the Patent Office of the United States Government, which will be of unusual size and interest. No fewer than 361 models of electrical devices, apparatus, machinery and appliances will be shown, many of them embodying the fundamental and elementary idea upon which the modern electrical arts have been founded. Cornell University will exhibit a Gramme dynamo built by Prof. W. A. Anthony in 1876, and exhibited at the Centennial Exhibition of that year. It is probably the first dynamo of practical form constructed on those lines in this country. The University will also show many other things of interest. The Western Union Telegraph Company has placed at the disposal of the Exhibition authorities two of its wires, over which a portion of the current developed at the Niagara Falls power plant will be brought to the Exhibition Hall for the purpose of operating the model of the plant itself; and it is also proposed to charge storage batteries by the same power at the Falls themselves, ship them to New York and use their energy in operating the model during the daytime when the wires are in constant use by the telegraph company. The wires will be used in the manner above mentioned at night only, when the regular telegraph business is slack. The object of using storage battery current for the operation of the model during the day is, of course, an extension of the idea of operating the model at all times by the power generated by the Falls. This exhibit will be remarkably interesting as illustrating the flexibility of electrical power transmission. Another interesting feature of this particular exhibit will be the transmission from Niagara Falls to New York by telephone of the roar of the Falls themselves, which was more particularly noted in a recent communication to *The Electrician*. Another interesting historical exhibit will be that of the College of the City of New York, and will include Prof. Joseph Henry's own experimental induction coil, and many other rare scientific curios. One of the cells of the historical old 500-cell battery used at the College of the City of New York will also be shown. Mr. A. B. Chandler, President of the Postal Telegraphic Cable, has loaned the Exhibition an interesting frame of very early relics of the telegraph in this country. Mr. E. J. Hall, Vice-President and General Manager of the Long-Distance Telephone Company, will loan some original long-distance telephone apparatus, including the instruments used by Prof. Alexander Graham Bell at the opening of the New York and Chicago line. The Gedney Channel electrical buoys, which at night light the way to the New York Harbour, will be represented in miniature, and will be in practical operation. Mr. W. J. Hammer will also show his celebrated collection of incandescent lamps illustrating the history of the art of lamp making. Other telegraph and electrical apparatus of historic value will be on view during the period of the Convention.

**The General Electric Company.**—This concern issued its fourth annual report last week. It shows a net profit of $877,645.49 for the year ending January 31, 1896. The financial statement is a very lengthy one, and in form differs somewhat from the previous report, which makes a comparison between the two rather difficult. However, in general the last report is considered favourable to the Company.

## CORRESPONDENCE.

### THE EWING PERMEABILITY BRIDGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the interesting account of Prof. Ewing's permeability bridge, which you published in your last issue, it may not be out of place to describe an apparatus based upon the same principle, though different in certain particulars, which Mr. B. H. Bedell has been engaged upon at my suggestion for the last six months in the physical laboratory of this College.

The test-piece, A B, is fitted to two circular end discs of soft iron, shown in section. It is placed at the common axis of three cylindrical coils, *a*, *b*, *c*, of which *b* and *c* are wound with the same number of turns each, and are connected in series, so that a current passed through them circulates round A B in opposite directions.

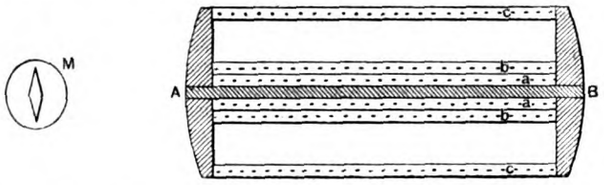
Currents $c_1$ and $c_2$ are then passed through *a*, and through *b* and *c* respectively, in such directions that the lines of force produced by *a* in A B are drawn back through the air space

Digitized by Google

between $b$ and $c$; and by suitably adjusting $c_1$ and $c_2$ the difference of magnetic potential between A and B may be reduced to zero, and this condition indicated by the compass needle M. In fact, the air space between $b$ and $c$ takes the place of the standard bar in Prof. Ewing's apparatus.

By using air in this way as the standard substance instead of iron, it seems to me that a certain simplification is obtained. For the current $c_1$ is obviously proportional to **H**, and $c_2$ to the induction in AB, *i.e.*, to **B**, so that ammeters inserted in the circuits of $c_1$ and $c_2$ may be made to read direct to the corresponding values of **H** and **B** by suitably numbering their scales. Moreover, the instrument is "absolute," in the sense that both **H** and **B** may be obtained from its dimensions and winding by calculation, $c_1$ and $c_2$ being known.

By the use of sliding resistances in the two circuits a complete curve, up and down, may be taken in a few minutes; this, however, is a property which is also shared by Prof. Ewing's instrument.



A small error arises from the fact that the lines of force drawn back by $c_2$ include a few air lines, which pass outside the test piece in $a$. It is almost negligible, but may be completely overcome by winding on the coil of the ammeter in the $c_2$ circuit a proper number of opposing turns and passing $c_1$ through them.

It is more than likely that Prof. Ewing has already contemplated the use of air as the standard substance, and rejected it in favour of iron. He does not refer to it, however, and this must be my apology for pointing out what is, after all, a fairly obvious form of permeability bridge.—Yours, &c.,

A. P. Chattock.

Physical Laboratory, University College,
Bristol, May 11, 1896.

## TRANSPARENCY OF FILAMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: With reference to a letter which appeared in your columns a week or two ago about the transparency of incandescent lamp filaments when hot, I have noticed in frosted lamps with plain horseshoe (*i.e.*, not looped) filaments a sharp distinct shadow of the filament all round the bulb, which would appear to indicate that the filament is opaque. The lamps referred to are run at about $2\frac{1}{2}$ watts per candle-power.—Yours, &c.,

G. C. Allingham.

Eldon House, Lyndhurst-road, Hampstead, N.W.,
May 11th.

# LEGAL INTELLIGENCE.

### Clarke v. Julius Sax and Co. (Limited).

This case came before the Court of Appeal, consisting of Lords Justices Lindley, Lopes and Kay, on Monday last, for judgment on the appeal of Messrs. Julius Sax and Co. (Limited) from a decision of Mr. Justice North refusing to rectify the register of designs by striking off No. 206,870, registered by John Farrant Clarke, on the ground that it was not novel and that similar designs had been used before, the design in question consisting of a lamp for electric lighting intended for use outside shop windows so as to throw light upon the windows and articles displayed therein. The case was reported in *The Electrician* of May 1st.

Lord Justice LINDLEY, in the course of an elaborate-written judgment having referred in detail to the statutes and decided cases bearing on the subject, said that, using his own eyes, and attending to the evidence adduced on both sides, the conclusion at which he had arrived was that the design registered was nothing more nor less than an old and well-known lamp or lamp shade, with the omission of a part, which was wanted for gas or oil burners, but which was useless for an electric light. The old shape of lamp or lamp shade consisted (1) of a reflecting screen of the same shape as the reflecting screen in the registered design; (2) of a ventilating top, differing in no substantial particular from the ventilating top in the registered design; (3) of a chimney on the ventilating top, and which was omitted from the registered design, not being wanted. The omission of the chimney rendered it necessary to cover in the ventilating top; but it did not really alter the shape of the lamp or lamp shades. Mr. Clarke had, in his opinion, adopted a well-known lamp or lamp shade to electric lighting; but the shape was the old shape with the omission of a useless appendage. He (his Lordship) had no doubt that a combination of old shapes might result in a new or original design of shape; and if it was the result that design would be protected if registered under the Act. Nor did he say that even the omission of something from an old shape might not result in a new or original shape which might be protected. But when, as here, the old shape of an article well known in the United Kingdom, consisted of three shapes, of three parts placed one over the other, and the new shape was exactly like the old shape, except that the useless upper part was omitted, he could not say that the shape of what was left was new or original, or that the residuary shape had not been previously published. He came to the conclusion that the design in question being for shape, and shape only, though new in its application to electric lamps, was old in its application to other lamps, and was not one to which the Act applied. In those circumstances, in his opinion, the appeal must be allowed with costs, both in that Court and in the Court below, and an order must be made to remove the design from the register.

The other Lords Justices read judgments to the same effect.

# TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

**SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d. abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations.**

## NEW BOOKS AND EDITIONS.

*The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—*

"The Alternate Current Transformer," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. The New Edition is Now Ready. Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

Laboratory Notes and Forms.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d. Will be ready first week in June.

"The Work of Hertz."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"Electric Motive Power."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"Electrical Engineering Formulæ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"Practical Notes for Electrical Students."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition now ready. Price 2s., post free.

"Armature Windings of Electric Machines."—By H. F. Parshall and H. M. Hobart. This work has been compiled from Notes made by Mr. Parshall in his capacity as chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables. 30s., post free.

Digitized by Google

TENDERS INVITED.—The vestry of Hammersmith require tenders for (*a*) supplying and laying high-pressure and low-pressure cables and pipes, (*b*) supplying and erecting arc lamps and lamp posts, (*c*) supplying and erecting transformers and sub-station equipment, (*d*) supplying and erecting a 5-ton overhead travelling crane. Specifications, &c., can be obtained of Mr. A. H. Preece, 39 Victoria-street, London, S.W., and tenders must be delivered at the vestry offices, 57, Fulham Palace-road, Hammersmith, by noon of Wednesday, May 27th. Mr. W. P. Cockburn is vestry clerk. Some further information is given in our advertisement columns.

——— Tenders are required for the lighting of the City of Bucharest for five years. Tenders must be sent in to the Town Council by June 24th.

——— The municipal authorities of Cassa de la Selva (Gerona) invite tenders for the electric lighting of the public streets. Tenders to El Secretario del Ayuntamiento de Cassa de la Selva (Gerona), Spain.

TENDERS ACCEPTED.—For providing and fixing telephones, electric bells and fire alarms at the Brook Hospital and Ambulance Station the following tenders were received by the Metropolitan Asylums Board :—

| | |
|---|---|
| Cox-Walkers *(accepted)* | £658 |
| Single-Wire Multiple Telephone Signal Company | 2,244 |
| National Telephone Company | 2,032 |
| C. E. Zimdars | 1,900 |
| Julius Sax and Co. | 1,657 |
| W. Seymour | 1,500 |
| Strode and Co. | 1,433 |
| Furse (W. J.) and Co. | 1,024 |
| Vaughan and Brown | 1,010 |
| Private-Wire and Telephone Installation Company | 1,009 |
| Consolidated Telephone Construction & Manufacturing Co. | 784 |
| Mason, Wathes and Brown | 722 |
| Tabor and Hinchcliffe | 706 |
| L. Alwyn | 662 |
| Pearson's Automatic Fire Indicator Company | 572 |
| Brown and May | 534 |

——— The Hampstead Vestry have accepted the tender of Messrs. S. Z. de Ferranti (Limited) for the supply of a steam alternator and switchboard, at £3,397. Eleven tenders were received for the supply of a feed-water heater and steam pipes, and six for the supply of a tank and appurtenances. The tenders of the Brush Company were accepted at £942 and £408. 10s. respectively.

——— The Brighton Town Council at their last meeting discussed the tenders received for supplying 80 arc lamp standards and 100 double-carbon arc lamps. The Electric Lighting Committee's recommendation was that Messrs. Hart, Son, Peard and Co.'s tender should be accepted for the former at £2,500 (and £31. 5s. for each additional post ordered), and Messrs. Crompton and Co.'s tender for the latter at £2,200 (including the fixing of 95 lamps). A number of tenders had been sent in for the standards, amongst which was one from a local firm (Messrs. Reed and Son) for the sum of £2,460, and the Council, after discussing the Committee's recommendation, decided to give the contract for the 80 standards to the local firm at the figure quoted (£2,460).

——— The Oldham Town Council have accepted the tender of Messrs. W. A. Shaw and Co., Stockport, for wiring the new technical schools. About 30 tenders were received by the Technical Education Committee for the work.

——— The Sunderland Corporation have accepted the tender of Mr. Joseph Home, of Hartlepool, for extensions to the electricity supply station building at £1,418, and the tender of the Westoe Foundry Company for erecting iron roofs for £189.

——— The Bradford Town Council have accepted the tender of Messrs J. Moulson and Sons for the construction of a reservoir and tank at the Valley-road electricity works at £890, in place of the tender of Messrs. Broxup and Sons, who had declined to proceed with the work.

——— The Cheltenham Town Council have accepted the tender of Messrs. McDowall, Steven and Co. for the supply of 25 arc lamp standards at £9. 15*s.* each.

APPOINTMENTS VACANT.—An engineer is required to take charge of the electric light installation at New Scotland-yard. Salary 50s. a week, rising to 60s. Applications to the Receiver for the Metropolitan Police District, New Scotland-yard, S.W. Further particulars will be found in our advertisement columns.

——— The Municipal Technical Institute of the Borough of Salford invite applications for the post of (1) Chief Lecturer in Chemistry (salary £200); (2) Chief Lecturer in Dyeing (£150); (3) Art Master (£220); (4) an instrument maker (£2 per week). Some further information is given in our advertisement columns, and all particulars can be obtained of the secretary at the Institute, Peel Park, Salford.

DISSOLUTION OF PARTNERSHIP.—Messrs. Harry Patterson and George James Harford, electricians, 49, Moorfields, London, E.C., have dissolved partnership.

REMOVAL NOTICE.—The I. E. S. Accumulator Company (Limited) have removed from Palace Chambers, Westminster, to 3, Delahay-street, Westminster, London, S.W. The Company's new telephone number is 3384 ; telegraphic address, "Lucubrate, London." The works remain at Woking, Surrey.

LIQUIDATIONS.—It has been decided to wind up the Fareham Electric Light Company (Limited), and the Managing Director (Mr. J. Blake) has been appointed liquidator. This decision has been arrived at owing to the purchase of the Company's undertaking by the District Council.

——— A meeting is to be held at Messrs. Jackson, Pixley and Co.'s offices, 58, Coleman-street, E.C., on June 22nd, at 2 p.m., to receive an account of the winding up of the Boy Messengers and Electric Call Company (Limited).

THE JANDUS ARC LAMP.—We have just received from Messrs. Drake and Gorham, the sole agents for this lamp, a long list of testimonials from installers and users. These testimonials are practically all dated the current year, and show a uniform success for the lamp. The list should prove useful to the trade.

EXPORTS OF ELECTRICAL APPARATUS AND MATERIAL.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from May 6th to May 13th, with the ports of destination :—

*Argentina*—Buenos Ayres, £73; Pasages, £97; Rosario, £831. *Australasia*—Adelaide, £120; Albany, £2,634; Fremantle, £949; Rockhampton, £97; Sydney, £244; Townsville, £12; Wellington, £274. *Canary Islands*—Las Palmas, £50. *Belgium*—Antwerp, £30; Ghent, £18. *Ceylon*—Colombo, £12. *Channel Islands*—Jersey and Guernsey, £130. *China*—Shanghai, £228. *Germany*—Dantzig, £23; Hamburg, £820. *Egypt*—Alexandria, £38. *France*—Boulogne, £10. *Holland*—Amsterdam, £337. *Hong Kong*, £99. *India*—Calcutta, £292. *Japan*—Yokohama, £110. *Russia*—Libau, £83; St. Petersburg, £858. *Siam*—Bangkok, £184. *South Africa*—Cape Town, £496; Delagoa Bay, £170; Durban, £30; East London, £1,497; Port Elizabeth, £133. *Spain*—Granada, £37; Seville, £7. *Straits Settlements*—Singapore, £13. *Sweden*—Gothenburg, £61. *Uruguay*—Monte Video, £145.

*Foreign-Made Electrical Apparatus and Material.*—Foreign made goods have been exported from this country, as follows :—

*Australasia*—Brisbane, £42.

DUNCAN'S MANUAL.—We have received a copy of the 19th edition (1896) of the useful "Manual of British, Foreign and Colonial Tramway, Omnibus and Electric Railway Companies," issued by Messrs. T. J. Whiting and Sons, 7A, South-place, London, E.C, price 3s. 6d. The manual contains a vast amount of information compiled in handy form, and will be found of service to those seeking information relating to the *personnel* of the principal tramway, omnibus and electric railway companies. The information includes a digest of the last accounts published by the companies.

SCOTLAND.—Those of our readers who contemplate a visit to Scotland during the coming summer will find an official guide of summer tours, written by Mr. David MacBrayne, of much service. The guide gives time tables, list of fares, steamer routes, &c., and is embellished with a number of illustrations and several good maps. Copies of the guide can be obtained at 119, Hope-street, Glasgow.

---

ABERDEEN.—Negotiations are proceeding between the Town Council and the Harbour Commissioners in regard to the electric lighting of the quay. It is calculated that about 70 arc lamps would be required, and the cost of these would be about £800 per annum. The Commissioners are anxious to obtain electric current at a reduced rate, and it is probable that the Council will meet them in the matter.

ALLEGED FRAUD.—At the Mansion House, London, last week, Arthur Stephen Ford, described as an electrical engineer, of Ironmonger-lane, E.C., was charged, along with William W. Carne, Alfred Jacobs, Julius Bellot, Charles G. H. Teniswood, and Adolphus Dresel, with conspiring to obtain £1,500 from a Mr. Joseph Morrison, described as a merchant, of 63, Queen Victoria-street, London, by false pretences, and with inciting him to receive stolen property. The evidence showed that Mr. Ford and the prosecutor had had certain business transactions together, the prosecutor having lent Ford about £300. On making application for payment, the defendant, it was alleged, offered to dispose of three £1,000 banknotes, which had been stolen in 1893 from the Bank of Scotland, suggesting that the prosecutor should release him from his debt, and pay him a certain sum, taking over the three £1,000 notes in settlement. This the prosecutor appeared to agree to do, but at once communicated with the City police. The defendants denied any knowledge of the business whatever.

Digitized by Google

The case had not proceeded far before Teniswood and Dresel were discharged from the case, and at the adjournment on Wednesday the others were admitted to bail in their own recognizances. The case was proceeded with yesterday (Thursday), when the cross-examination of Morrison was resumed, Mr. Raphael, the solicitor for Jacobs, contending that no reliance should be placed on his evidence, and that he had conducted a fictitious business, a statement which Morrison denied. In the end the Lord Mayor dismissed the charge against all the defendants.

Asylum Lighting.—The Governors of the Armagh County Asylum, recognising the many advantages of the electric light, have decided to put in an installation at the new asylum building. A committee has been formed to settle details and to supervise the execution of the scheme.

Autocars.—A meeting was held on Monday at Walsall of the manufacturers of Birmingham and Walsall in the trades likely to be affected by the introduction of the autocar into general use. Amongst the resolutions approved were the following:—That the rate of speed in towns should not exceed five miles per hour and 10 miles in the country; in the case of a horse-drawn vehicle meeting an autocar in a road too narrow for them to pass, the autocar to give way; that while any tax remains on horse-drawn vehicles this tax should equally apply to the autocar; that all autocars be numbered. These suggestions were unanimously approved, and it was decided to form an association, called the Road Safety Association, to urge the embodiment of the above suggestions in the Locomotive and Highways Bill now before Parliament.

Bath.—The City Council have decided to adopt the recommendation of the Electric Lighting Committee to purchase the undertaking, machinery, &c. (except the arc lighting plant) of the City of Bath Electric Lighting Company, on the terms of Prof. A. B. W. Kennedy's report, an abstract of which appeared in our last issue. The Company, however, strongly object to the terms of the transfer, as they contend that the arc lighting plant should also be taken over by the Corporation at Prof. Kennedy's valuation, viz., £1,954. With a view to settling this point, at the invitation of Sir Courtenay Boyle, K.C.B., a conference was held on Monday last at the Board of Trade between representatives of the Company and the Corporation. The Company was represented at the Conference by Mr. Sydney Morse, who submitted that the arc lighting plant should be taken over by the Council, as it would not be of the slightest value to the Company if left on their hands, and that some allowance ought also to be made for the very heavy preliminary expenses (£4,512) which the Company had incurred. Sir Courtenay Boyle's decision was adverse to the Company on both points. An early meeting of the Council is to be held for the purpose of arranging for the completion of the purchase.

Bangor.—In consequence of the refusal of the Board of Trade to grant the Town Council's application for an electric lighting licence the Manchester Edison-Swan Company have already given notice of their intention to apply for a Provisional Order. From the evidence adduced at the recent Board of Trade inquiry it is considered that an electricity supply station would prove successful, and the Manchester Edison-Swan Company are prepared to make the most of the Council's lost opportunities. The Company's application may, however, be objected to, as the majority of the Council are still anxious, notwithstanding the strenuous opposition of the gas interest, to establish electricity supply works.

Beauly (Rossshire).—In view of the arrangements for the installation of the electric light at Beaufort Castle, some of the principal residents are making inquiries as to the practicability of lighting the village electrically. It is considered that sufficient water power can be obtained from the Falls of Kilmorack, and an electrical engineer has been commissioned to prepare a report on the matter.

Blackburn.—The Electricity Committee intend to apply to the Local Government Board for sanction to borrow £10,000 for electric light extension purposes. In consequence of the Committee having received a number of applications from the Preston New-road district, and from people who have hitherto employed their own generating plant, the capacity of the plant at the station has been practically exhausted, and the extensions will have to be carried out immediately.

Cheltenham.—The Electric Lighting Committee have decided to put in a new boiler at the electricity supply station. The applications for current continue to come in, and at the present time there is an equivalent of 6,609 8-c.p. lamps connected, while 600 or 700 more are waiting to be supplied.

Country House Lighting.—Sir William Arrol intends to instal the electric light at his residence, Seafield, near Ayr, and current is to be taken from the Corporation mains, the Council having decided to make the necessary extension.

Darjeeling (India).—Some time ago we referred to the proposal for the erection of electricity supply works in this town, and from latest advices we learn that the Bengal Government has now approved the plans and estimates of the scheme.

Fareham.—Mr. E. Manville has presented his report to the Council on the condition of the electric light works. The cost of putting the wires underground and of altering the position of certain of the lamps is put at £1,428, and the Council are further recommended to duplicate the plant at the station at a cost of £1,025. The Electric Light Committee approved of these suggestions, but the Council have decided to refer the matter back for further consideration.

Fulham (London).—Mr. F. H. Medhurst has prepared an elaborate report on the proposed joint electric lighting and refuse destructor scheme. The Vestry are recommended to apply for a Provisional Electric Lighting Order, so as to be in a position to proceed with both projects simultaneously. Mr. Medhurst is of opinion that the high-tension alternating-current system, with a low-tension network of mains for private supply, would be best suited to meet the requirements of the district, and by utilising the energy produced by the combustion of the refuse the cost per unit would not exceed 2·3d. The total capital outlay, including the erection of a 14-cell destructor and the erection and equipment of electricity supply works capable of generating 372,000 units per annum, would be £54,000. The working expenses, sinking fund, interest, &c., would come to £7,700, and the estimated revenue to £9,953, leaving a profit of £1,659.

Glasgow.—Prof. Becker, who has for some time been experimenting at the Observatory with electric clocks with the view of putting in an installation to give uniform time to the whole city, has presented a report recommending the removal of the present installation at the Observatory to the Municipal Buildings, from which, by way of experiment, a central area with 10 wall timepieces will be worked. In the event of the experiment proving satisfactory the system will be extended.——The Electro-Magnetic Traction Company of Philadelphia, through their local representative, have offered to equip from three to five miles of the Corporation tramways on their underground system of traction as an experiment. The proposal is at present under the consideration of the Tramway Committee.

Halstead (Essex).—Messrs. Crompton and Co. have submitted to the District Council plans and specifications of a scheme for the electric lighting of the district. The matter is under consideration.

Harrogate.—The Town Council have decided to apply to the Local Government Board for sanction to borrow £30,000 for electric lighting and other purposes.

Hotel Lighting.—The Three Nuns Hotel, an extensive building at Aldgate, London, is now lighted electrically, current being supplied by an independent plant.

Islington.—The Vestry have now decided to proceed with the scheme of electric light extensions referred to in our issue of the 17th ult. The minutes of the Electric Lighting Committee, presented at the last sitting, contained the following recommendations:—(1) That it be referred back to the Committee to at once take steps for placing orders for the additional plant mentioned in the report recently presented by the electrical engineer (Mr. Albert Gay), and for the necessary extension of the station to accommodate the plant, at an estimated cost of £23,750, in order that it may be running by next winter; (2) that the mains be extended from Seven Sisters-road to the "Archway" Tavern, Highgate Hill, at an estimated cost of £5,000; and (3) that conduits and mains be at once laid in the Caledonian-road, at an estimated cost of £9,000. In reference to the latter recommendation, it was stated that several applications has been received from the Caledonian-road district, including one for an equivalent of 3,000 8-c.p. lamps. The Committee's recommendations were agreed to. In addition to these extensions the question of laying mains in the Essex and Camden-roads (almost the two extremes of the Vestry's area) is under consideration, and, if the proposals before the committee are carried out, will involve an estimated outlay of £6,549 and £4,035 respectively. Although the Vestry only commenced to supply current for private purposes in March last there is already an equivalent of 7,436 8 c.p. lamps connected, while 30 or 40 customers are waiting to be connected. The capacity of the present plant is 14,000 8 c.p. lamps, but the additional machinery proposed to be put down will increase this figure to 30,000. It is seldom that such an elaborate scheme of extensions has to be undertaken within three months of the commencement of supply, and we understand that still further extensions are under consideration.

Kingswood (Bristol).—The District Council have received an offer from the Town and Village Electric Light and Power Company to dispose of their electricity supply works, and the matter has been referred to the Lighting Committee for consideration and report.

Kirkcaldy.—A project is on foot for the introduction of the electric light into Kirkcaldy, and a scheme for the construction of an electric tramway between Kirkcaldy and Dysart is also being formulated.

Merthyr Tydfil.—The Board of Trade have granted Mr. J. C. Howell's application for a Provisional Order for this district, but

Digitized by Google

the radius of the area of supply has been reduced from a mile to half-a-mile of the centre of the town. The District Council have approved the restriction.

MIDDLESBOROUGH.—A recommendation by the General Purposes Committee that no further action be taken at present in the electric lighting question led to a long and animated discussion at the meeting of the Town Council on Tuesday last. Alderman Jones moved that steps be at once taken to establish electricity supply works at an estimated outlay of £21,000, and contended that the Council ought to follow the advice of their consulting engineer (Mr. R. Hammond), who recommended them to erect a supply station forthwith. The discussion of the matter was adjourned.

MILL LIGHTING.—Messrs. Sewell and Hulton's mill, Pendleton, is to be lighted electrically.

MUCH WOOLTON (LANCS.).—The District Council have received a letter from the Board of Trade relative to the inquiry recently held by Major Cardew into the application of the Liverpool District Lighting Company for a Provisional Order for Much Woolton, Garston, Allerton, &c. Major Cardew, it is stated, recommended that the Company be allowed to make a maximum charge of 10d. per unit, and that a clause be inserted in the Order providing for a revision of the charges at the end of three years. The Council have approved the Company's application.

NEWPORT.—The demand for electric current continues to improve in a promising manner. The Harbour Commissioners have decided to take current from the Corporation for lighting the new excursion pontoon.

NORTHAM (WESTERN AUSTRALIA).—The Electric Power Company have decided to erect their works at this town, where a huge dam for the Company is being constructed on the Mortlock River, tests having proved that the bed of the river carries strong supplies of permanent water.

OSTEND.—It is stated that, notwithstanding the death of Col. North, it has been decided to complete his big scheme at Mariakerke, in the western district of Ostend, which includes an electric railway amongst other features. The whole of the work is to be completed in two years.

PARIS.—M. de Selves, the Director General of French Posts and Telegraphs, and who was a delegate to the International Telegraphic Conference at Paris in 1890, has been appointed Prefect of the Seine. In this position he will have much influence on the future of French telephonic improvements, a subject in which M. de Selves takes a great interest.

STAFFORD.—The Town Council recently offered to supply current for the electric lighting of the County Council buildings at 8d. per unit, but the County Council have decided to put down an independent generating plant unless current can be obtained at 5d.

ST. GEORGE'S (HANOVER-SQUARE, LONDON).—The Special Committee recently appointed to consider the electric lighting and refuse destructor questions have presented a report in which it is recommended that no further action be taken at present owing to the large initial capital outlay involved, viz., £70,000. The Vestry are, however, advised, in the event of the neighbouring Vestry of St. James adopting the electric light, to try the experiment of extending the mains from Piccadilly to Knightsbridge at an annual cost of £1,230.

SUNDERAND.—The Town Council have decided to reduce the charge for electric current from 6d. to 5d. per unit.

SWANSEA.—The Electric Lighting Committee are endeavouring to revive their joint electric lighting, tramway and dust destructor scheme, and with this object negotiations are at present in progress between the Committee and the Tramway Company. Both parties are anxious to come to an agreement, the Committee because they wish to see electricity works established in the town, and the Company because they desire to introduce some improved system of mechanical traction on the tramways. In the event of the negotiations not having a satisfactory termination the Tramways Company intend to approach Mr. J. C. Howell, who recently offered to take over the Council's Provisional Order.

TELEPHONE TRUNK LINES.—Replying to a question in the House of Commons as to whether the Post Office is now prepared to give the same facilities for using trunk telephone lines (with respect to hours of service, &c.), as existed previous to the Post Office taking over the lines, Mr. Hanbury stated that to the north of the Thames the old facilities remained, as the National Company still worked these trunk lines, under Post Office control. Facilities are now being experimentally given in the South of England, and this experiment is about to be extended. Until the result is known no pledge could be given as to the permanent character of the arrangement. In connection with this subject, the Post Office announces that with a view to afford facilities for telephone trunk wire communication at night and on Sundays at places where the post offices are not open continuously, it has been decided that trunk circuits are to be switched through at the post offices to the National Company's exchanges, one end of each circuit being retained at a post office at which a continuous service is given. This post office will be known as the "controlling" office. The arrangements have been made so as not to prevent the trunk circuits being used at the post offices at any hour of the night or on Sundays, and these special arrangements will terminate on the resumption of trunk working on the following morning if a week day, or, in the case of Sundays, when trunk working is resumed on Monday morning. The arrangement comes into operation forthwith at the following offices:—Bath, Weston-super-Mare and Taunton ("controlling" office, Bristol); Totnes and Dartmouth (Exeter); Torquay (Plymouth); Bournemouth and Winchester (Southampton); Worthing, Newhaven, Lewes, Eastbourne and Hastings (Brighton); Reading, Slough, Guildford, Sevenoaks, Tunbridge Wells, Gravesend, Chatham, Maidstone, Canterbury and Sittingbourne (London); and Ramsgate and Sandwich (Dover).

TRAMWAY RAILS.—The adoption of electric traction for tramways renders any device for reducing the cost of the construction of permanent way of general interest to our readers. It is stated that the Leeds Corporation are experimenting with a new type of tramway rail designed by Mr. W. Towler. This rail is in two pieces, the upper portion of which can be removed and replaced when worn without disturbing the lower section. By bending the flanges of the upper section so as to clip the head of the under rail, the two sections can be securely held. There are a number of advantages claimed for this arrangement, including simplicity of construction, the saving of time, labour, and interruption of traffic in the relaying of worn rails, and especially economy, as it is estimated that the upper section of the rail can be replaced at the cost of a little over £500 per mile, against the present cost of over £1,700 per mile.

TUNBRIDGE WELLS.—The Borough Electrical Engineer's report presented at the last meeting of the Council proves that the electric light is making steady progress. In October last there was only an equivalent of 740 8 c.p. lamps connected, but on March 31st this number had increased to 7,024. The accounts for the half-year showed that a profit of £737. 13s. had been made, and the working cost only amounted to 2·27d. per unit.

WALSALL.—Owing to the rapid progress made by the electricity supply works considerable extensions will shortly have to be made in order to meet the increasing demand for current. The Council have decided to aquire so much of the South Staffordshire Tramways Company's system as lies within their jurisdiction.

WELLS.—The City Council have succeeded in placing themselves in an embarassing position over the public lighting question. First of all it was decided to purchase the Gas Company's undertaking, but early in March last the Council passed a resolution in favour of the establishment of electricity supply works and of borrowing £16,000 for that purpose. A special meeting of the Council was held on Monday last to clear up matters, when it was decided to obtain parliamentary sanction to their decision to purchase the gas undertaking and to postpone the electric light question for a time.

## COMPANIES' MEETINGS AND REPORTS.

### Western and Brazilian Telegraph Company (Limited).

The thirty-first ordinary general meeting of this Company was held yesterday at Winchester House, Old Broad-street, London, under the presidency of Mr. W. S. Andrews.

The SECRETARY (Mr. R. M. Cunningham) read the notice calling the meeting and the minutes of the thirtieth ordinary general meeting, held in November, 1895. The report of the Directors was taken as read.

The CHAIRMAN said: Gentlemen, there is very little for me to tell you this half year, the period having been pretty uneventful. As usual, I will deal with the receipts first. Our takings have been £80,315, as compared with £82,815 in the corresponding period of the previous year, showing a reduction in the past half year of £2,500. You would naturally suppose that that means a falling off in our trade, but that supposition would be erroneous. As a fact, although the amount of money received is smaller the business transacted has been larger. We have had the same unpleasant experience repeated this time from which we have had to suffer before. It is unfortunately not a new experience that, partly from losses in exchange and partly from other causes, our messages produced less. Of course, it would be more satisfactory to come before you with an increase of receipts than a diminution, because you would have the loss per word of the decreased number besides the loss on exchange. We have not had an increase by leaps and bounds, but there has been a moderate increase pretty well all round, and the average of it comes out at 10½ per cent. on the number of words, including the business from the West Coast of South America, which has continued to increase in a very satisfactory manner. The

Digitized by Google

reason of the loss in money, although the increase of traffic has continued, we must seek in the reductions in the tariffs that have been made from time to time, and from the still further loss which has been sustained in exchange, particularly during the half-year under review. I daresay you will be rather surprised when I tell you—what I have had to tell you before—that, as compared with the par of exchange, ourselves and the Platino Company show an ingathering of £40,000 less than we should have done at the par of exchange. Of course that means a lot of money and also a lot of dividend that we lose, but it arises from a cause which, unfortunately, it is not in our power to remedy. It is the old story, that with a satisfactory exchange we should have nothing whatever to complain of, because, owing to your assistance from time to time, we have been able to put by money enough to duplicate our lines, with the object, as we have said, of holding our own in attracting traffic. We have held our own very perfectly in that respect, because we have continually shown an increase in the quantity of business done. The only point where we have not succeeded, and where it has not been in our power to succeed, is that which is beyond our control altogether—namely, the exchange. As an illustration of the working, I have no doubt that you have seen in the newspapers a notice about the boat race. It was sent over the lines of the Eastern Telegraph, the Brazilian Submarine, and of this Company in something under a minute. I believe it reached Valparaiso, the terminus of the line, in 45 seconds. That is a distance of 8,700 miles, as the Managing Director justly observes. That sounds very wonderful, and I do not mean to say that all the staff concerned in the companies having to do with it do not deserve credit. They do; but it is not so wonderful as it looks, and for this reason. The line from end to end is practically one continuous homogeneous system. The clerks throughout the system are sitting in the same office. They are sitting at tables which are close to one another, and one man is working the apparatus here and another is working it there, so that really when the first signal appears from this end, say, the clerk on the left can see it immediately, and pop it on to the next station without the loss of any time at all. I see that a gentlemen differs from me in that, but practically the interval is so small that you may almost neglect it, and, therefore, the transmission was almost simultaneous, so to say, from end to end of the line. There are several transmissions, but it does not really matter very much. They all come on in such a way that they do not cause a loss of time. There is one thing we may deduce from the facts that I have just brought to your notice—namely, that from a business point of view this permanent contiguity of the clerks and the apparatus and the homogeneous working offer very distinct and considerable advantages to those who want to use our telegraphs. To that extent, therefore, it is highly satisfactory and encouraging. There is another fact which has occurred this half-year—that is, that the number of words per message has dropped again. It has fallen to nine, which, of course, adds somewhat to our expenses. I do not think I need deal further with the revenue account. If we turn to the expenses account we cannot, of course, expect to see a decrease in the expenses of our clerkage and so on, with more work to handle. Therefore the expenses under abstract A show an increase in clerkage of £1,276. Of course, this refers to the men who are occupied in Brazil—a very unhealthy climate, I am sorry to say—in earning our money for us. The maintenance under the same head exhibits an increase of some £1,497, but £474 of that was spent in connection with certain apparatus, and is non-recurrent, and £798 was spent on repairs to cables. We hired tugs near Monte Video when our ship the "Norseman" was occupied a long way off in the north. If we are so fortunate in the future as to have interruptions which cannot be dealt with in that we propose to make an alteration in the heading "B—the ships," and make it "B—ships and maintenance of cables," because we think that is the proper place to put an item of this kind. I may say with respect to this outlay that it is more economical than it would have been to wait for the repair till our ship was disengaged, and then to have sent her down from the north to the south—a distance of thousands of miles—at great expenditure of coal and loss of time. There is another apparent increase of £430, but that is really only a matter of account. Instead of charging the insurance in one sum in the year we have split it into two, and thus half of it appears this half-year instead of the whole of it in our next account. With regard to B—ships—I have nothing much to trouble you with. There is a small reduction of £129. There is an item of £555 for one of the ships which was laid up, but that will now disappear, so that I need not labour it. C, expenses in London, shows a small diminution of £94. In the general account we exhibit some further reductions which I do not propose to trouble you with, under the heads of cable for repairs, depreciation of the Norseman (of course there is less to depreciate there each year), and the item of the training school. The upshot of all is that the expenses show an increase of £1,718, as compared with those for the half-year to December, 1894. We bring down a balance of £42,192, to which we add £5,803 brought forward from the previous half-year, and £4,618, the dividend we received from the Platino Company. These items added together produce £52,614. Against this there has been a charge of £11,148 for debenture interest, £7,952 for debenture redemption fund, and after placing £3,000 to reserve, we are able to recommend a dividend of 5s. 3d. a share, carrying £4,952 to the current half-year. You have noticed, of course, that the dividend now recommended, with that paid for the previous half-year, makes an average of 3 per cent. for 1895, or the same amount as was paid in 1894. I wish we could have done better; but I must confess that at times I feared we should not be able to do so well. With respect to the current period, I think I ought to say that it is likely to turn out less favourably than the half-year we are dealing with. The exchange all through has been lower, and has reached what we hope will prove a record price; and the business, besides, has not shown the same growth and elasticity as it has done all the half-years we have had to deal with up to the present time. There is no doubt that a good deal of this arises from the fact of the recent severe illnesses in Brazil. We have been very unfortunate ourselves in loss of men, and merchants have actually closed their offices and gone up into the interior because the risk to life has been so great. In fact, the period has been one of extreme distress all through the country. I daresay you saw an account in the newspapers of an Italian man-of-war at Rio, who lost half of her crew, including all the officers. There is no doubt that we are passing through a period of great difficulty, and consequently we are experiencing more or less the trouble that always comes of difficulties; but, at the same time, I do feel that at the back of all this there is a big potentiality. We are dealing with a country of enormous magnitude—a country possessing immense capacity for progress, and one which I think most people will agree with me is bound to improve. You have india-rubber, coffee, cocoa, corn, cattle—all sorts of those things which the world wants are produced in Brazil, and that is a fact which must tell in time. I believe that eventually the United States of Brazil will emerge from all her trouble, and take up that great commercial position which, in my opinion, is awaiting her. We fortunately continue on excellent terms with the Government, and our exertions are always directed to the object of maintaining and improving our present very excellent relations. No doubt you have noticed the paragraph in the report with respect to the ships. You know that we were left with two of them laid up when we bought the new "Norseman" with the object of being enabled to do with only one ship. We have sold the "Viking" at a fairly satisfactory price, and I believe that the purchaser has got a very excellent and a very cheap ship. We had to spend some money upon her because it was necessary, of course, for her to preserve her classification as A1 at Lloyd's, and that she did. Then we thought we might succeed in getting a charter for the "Norseman," but I regret to say that she did not turn out well when she came to be examined, and our surveyor strongly advised us to spend no more money on her. We had had no advice of such a character previously, but on a very thorough examination being made of the ship, it seems that her ribs had been very much strained, distorted and injured in a great storm she was in on the coast of Brazil. They reported that so much injury had been done to the ship that it would cost as much to repair her as to buy a new vessel, and she had to be sold at a considerable loss, which has been written off the reserve fund. We have a small balance to receive of £1,399, and that will complete the account as regards these ships, which we have to maintain, so to say, for no purpose. They will disappear from our accounts, and the item which you have seen from time to time of maintenance of ships in dock will disappear with them. We have only got our one steamship, which is a very excellent vessel, and does her work wonderfully well. There is no change as regards the purchase of our lines by the Government, and, as far as one can see—this is a matter of personal opinion—I do not think there is likely to be much change in the present position unless there is a considerable improvement in the finances of Brazil. When that takes place we have no reason to believe that this question will not be revived; in fact, it is still in a state of torpid existence. The power of purchase remains. My impression is that it will be continued until the Government are ready to deal with the question. There is another little crumb of comfort—although only a small crumb—namely, that exchange seems now to be improving. I believe there is a good coffee crop—the largest they have had for a long time—and that will bring more active business, and send more money into the country, and we are told that the exchange is improving. A Telegraph Conference to consider telegraph matters is to meet in Buda Pesth in June. It is a conference of all the States and parties interested in telegraphy, and as usual they have invited the companies and given them a deliberative voice in the Conference, although, not being parties to the treaty, our Company has no voice. I do not think anything is likely to occur there of any considerable interest for us, but we shall be represented, and everything will be watched in our behalf. I have nothing further to add, except to propose—

*"That the report and accounts to December 31, 1895, now submitted, be and are hereby approved and adopted, and that a dividend of 5s. 3d. per share, free of income tax, making, with the interim dividend paid in November last, £3 per cent. for the year 1895, be and is hereby declared payable on the 15th inst."*

Mr. C. W. EARLE seconded the motion.

Mr. W. GRIFFITH thought it matter for regret that the Chairman had not been able to give them any assurance that the Brazilian Government really intended to carry out the very important proposal which had been made to them for acquiring their undertaking. Would it not be possible to charge higher tariffs and thus recoup the loss they sustained by exchange?

Mr. A. R. GRANVILLE asked a question relative to the amount of depreciation of "Norseman No. 1."

The CHAIRMAN: We dealt with this matter in 1894. You will notice in the reserve fund account that we say, "Depreciation written off 'Norseman' B No. 1," £13,100. This exchange business and the increase in tariffs have had the most careful attention of the Directors and of everyone else interested in the traffic, but our difficulty lies in this—that we are not the only line. As has been said, we are open to competition, and if we were to put our rates up and the others did not do so, we should lose the trade. Until, therefore, we can succeed in persuading our competitors to put up their rates to cover their loss by exchange, we cannot do it.

A SHAREHOLDER inquired whether the Company's revenue benefited by the Amazon Telegraph.

The CHAIRMAN: Yes, to the extent of the traffic it will do so.

Lord Richard H. Browne and Mr. John Coppen were then re-elected Directors, and Messrs. Turquand, Youngs, Bishop and Clarke as auditors.

A cordial vote of thanks to the Chairman, Directors, Managing Director, and Staff terminated the proceedings.

Digitized by Google

## Brazilian Submarine Telegraph Company (Limited).

The forty-fifth *ordinary* general meeting of the shareholders of the Brazilian Submarine Telegraph Company (Limited), was held in Winchester House, Old Broad-street, on Wednesday last, Lord Sackville A. Cecil presiding.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting and the minutes of the previous meeting, the latter being signed as correctly entered by the Chairman.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: Gentlemen, before we proceed with the ordinary business I am sure the first thing which will strike you for remark is the absence *from* the chair of Sir John Pender, and I am confident that I am only anticipating your wishes in giving expression on behalf of this meeting to the feelings of sincere sympathy with him and his family felt by all here present *under* the circumstances of his long-continuing and dangerous illness. It is but a hackneyed phrase that Sir John Pender's name is a household word in submarine telegraphy, and although he only joined this Company officially at the death of the late Chairman, Sir James Anderson (himself a man of world-wide renown), some three years ago, he has been interested in this Company, as he himself told us at one of his early meetings, from its very foundation; and we felt that his acceptance of the chairmanship when it fell vacant did equal honour to this Company and to himself. From his connection with our allies, from his grasp of the large problems of international telegraphy, and from his intimacy and acquaintance with all concerned in this great branch of scientific and commercial progress, he was peculiarly fitted to represent this Company. We miss his accustomed presence here as a personal loss, and we will wish him what I am pleased to be assured he enjoys as far as possible, a full measure of comfort and contentment. This, gentlemen, as you will remember is our interim meeting. You will agree with me that it is not opportune to discuss large and important questions of policy which must ever be watched by your representatives on the Board, and, indeed, I doubt if their discussion at shareholders' meetings is very profitable for the interests of any company. At the same time we have nothing in our accounts to hide; and if, after moving the usual resolution, any proprietor thinks fit to ask me questions with respect to the accounts, it will most certainly be my desire to give him in reply such information as seems proper. With your leave I will now turn to the report and accounts, which you have taken as read. In paragraph 2 of the report you will see it stated that the receipts for the half-year ended December 31st last were £106,168, which is a decrease of £2,038 upon the previous half-year, although an increase of £1,242 on the corresponding half-year of 1894. The decrease of message receipts is—to be precise—£2,104, and the figure £2,038 is reached by slight adjustments of interest and transfer fees, which are £66 more. There were satisfactory increases in the receipts from our traffic with the West Coast of Africa, the Cape of Good Hope and other South African Colonies and States, and also with the West Coast of South America. The falling off in receipts has arisen on the east side of South America, that stretch of country represented on the map by the sea board of Brazil, Uruguay and Argentina, and it is sufficiently accounted for by the fact that for four months of the half-year, viz., from September 1st to December 31st, the charges from this side of the Atlantic were reduced by 70 centimes, or nearly 7d. a word. The decrease which would have resulted from that reduction would have made a much larger inroad into our total traffic receipts but for the improved rate of average value of the Brazilian currency, in which a large portion of our income is collected, and also for some slight compensation in the increased volume of the traffic carried. I should like here to say a few words about some considerations upon the limits of compensation for low rates which may be desirable from increased volume of traffic arising in consequence. It is a subject upon which there is still a great deal of misconception outside the small circle of those immediately engaged in the conduct of telegraphic business, The general subject was treated some years ago by the late M. Vinchent, who has been regarded as the pioneer of cheap telegraphy in Belgium, whom it was my good fortune to know personally. He has left a record of his investigations which is still cited as canon with regard to overland telegraphy. Most of his conclusions then arrived at apply with extra force to submarine cables on account of their much greater cost of construction. It is most to be wished that all who approach this subject should appreciate that there is not much real analogy between the results to be anticipated from lowering postages or carrying rates of commodities and those of lowering telegraph rates, and any inferences drawn from analogy between them require most careful scrutiny. A cable once full you have to lay down another, just like building an entire new railway, or constructing a new road from end to end of your system, at large initial expenses, which new way has to be manned and maintained in addition to what already exists; and so after a certain turning point which in telegraphy may soon be reached, you have, besides the additional working expenses, to contemplate interest on freshly sunk capital. Those economists who may be aiming at universal cheap telegraphy for the social purposes of everyday life, had a great deal more before them than is always realised, and as regards the merchant—our chief customer, perhaps—he, with his registered addresses and codes, already possesses a larger measure of cheap telegraphy than, as a wise business man, he will hasten publicly to admit. These considerations lead up to the question of the best appliances for getting the maximum duty out of lines already laid, and your Board have lately entered into an agreement whereby we should obtain the use of quite the most modern automatic appliances for signalling through long cables. They are distinct advances on anything hitherto accomplished, and although they are rather costly we shall probably be obliged to bring them into use before long for the sake of the accuracy and increased carrying capacity we shall obtain. We are preparing generally for the unpleasant prospect of having to do the increase of our work at less profit, and personally I look for some increase on our working expenses in the future. I would simply remark here that in this industrial progress it is those equipped with the best machinery and backed with means who stand the best chance in the race. The total expenses chargeable against the half-year amounted to £21,623, which, compared with the previous half-year, were £494 more. There is a decrease in the London expenses of £371 and an increase in the expenses at stations of £289, and in other items of expenditure an increase of £576. The main item of increase of expenditure at stations is salaries and pension fund, and I am quite certain that the proprietors will not grudge their staff at foreign stations—Pernambuco, St. Vincent, and Madeira—the advantages they have now obtained of being put on a scale and in a position as regards pension in line with the staff of other companies. The increase in other expenses of £576 is entirely due to more repairs having been done to cables and shore ends. This item of cable repairs I need only remind you is an exceedingly variable one. It baffles all forecasting—and, I was going to say, control or calculation either. A fault may open up at any moment which will put the Company to an expense of thousands, or to even a more serious draft on the reserve. The last big fault which I recollect cost us, I think, between £8,000 and £10,000, to repair, and was nothing so very wonderful either as regards difficulty of the repair, though it was admirably done by the captain and crew of the ship "Mirror." I therefore make no apology for my colleagues and myself in having again placed a good sum to the credit of the reserve fund, or in view of competition, bad trade, and low exchanges, for having carried forward a rather unusually large sum to the credit of the current half which is the closing one of our financial year. This is not the half-year when your Directors come before their fellow proprietors for re-election, but in the absence of our Chairman through illness, and precluded as we are for the present from the advantage of Mr. Brodrick's assistance at the deliberations of the Board, he having accepted office in the Government, we feel that we shall have the hearty support of the proprietors in having elected Sir Albert Leppoc Cappel to a casual vacancy on the Board. Sir Albert has occupied the distinguished position of Director General of Indian Telegraphs, and has for many years been led to make the telegraphic communications of the world his peculiar study. In having gained him for a colleague on the board, we feel increased confidence in approaching the problems of the future which may be before us. We are on the eve of the Quinquennial Telegraph Conference at Buda Pesth next month, and some of the questions down for discussion are again very important for all the cable companies. We venture to hope that the submarine telegraph companies have now made good their claim to submit their views on such subjects, and that their views will continue to receive that consideration which is due to the representations of the largest and earliest pioneers of international telegraphy. Though not falling exactly within the limits of the half-year to which the accounts relate, I ought not, perhaps, to close without a reference to the Amazon telegraph extension to Manaos, which has been taken up with spirit, and the cables laid by the exertions of our allies, the Western and Brazilian Company. The line will act as a feeder to the joint undertaking, and will, we hope, settle down into a successful one. On this side of the Atlantic we have not been idle in the joint interest. Together with our allies, the Eastern Telegraph Company, and with the Telegraph Construction and Maintenance Company, we have joined in a new company called the German Telegraph Company, or, more correctly, the Deutsche See-Telegraph Gesellschaft, having for its object the laying of a cable from Emden in Germany to Vigo in Spain, whence there is a short cable to Lisbon, where our main cable diverges. That new cable is in course of construction, and when we next meet I hope we may be able to report further with respect to it, but if our hopes are realised it should carry a valuable North European traffic for our route, much of which is now lost to us. He concluded by formally moving the adoption of the report and accounts.

Mr. FREDERICK YOULE seconded the resolution, which was carried unanimously, and a vote of thanks having been accorded to the Board of Directors, for which the Chairman expressed his acknowledgment, the proceedings ended.

---

**MEMORANDA.**—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 31 1/16d. per oz. (May 14th). Consols (2½ per cent.) 111⅝—112 for money, 111 15/16—112 1/16 for account; 2½ per cent. 107⅞—107⅞ (May 14th). Stock Exchange Settling Days: Consols, June 1st; Stocks and Shares Continuation Day, May 27th; Ticket Day, May 28th; Pay Day, May 29th; Mining Share Carry-over Day, May 26th.

**ELECTROLYTIC PROCESSES.**—At the last meeting of the Camden Syndicate, on Tuesday, reference was made by the Chairman (Mr. W. A. Harper) to the formation of the Smelting Company of Australia (Limited), which had been established to take over the Syndicate's interest in certain electrolytic patents and processes for the treatment of all kinds of ores and the establishment of large central metallurgical works in Australia. He stated that the establishment of the Smelting Company's works had already led to great activity in mining in New South Wales, and, with regard to the electrolytic process for the recovery of zinc, he had visited Berlin and had satisfied himself that Messrs. Siemens and Halske had succeeded in obtaining zinc as cheaply, as simply, and perhaps more effectively than any other previously thought-out electrolytic scheme. Messrs. Siemens and Halske were now proceeding with the construction of the first instalment of their electrolytic plant for Illawarra, and that well-known firm were taking full responsibility for the success of the working of the plant.

## West India and Panama Telegraph Company (Limited.)

The report of the Directors of this Company for the half-year to December 31st last will be submitted to the general meeting, to be held at Winchester House, London, E.C., on Wednesday next, at 12 o'clock. The report states that the amount to credit of revenue is £33,558. 3s., against £33,243. 4s. 4d. for the corresponding half-year of 1894, and the expenses have been £19,676. 5s. 11d., against £23,613. 14s. 8d., leaving a balance of £13,881. 17s. 1d., which, with £1,421. 7s. 2d., brought forward, makes a total of £15,303. 4s. 3d., to be dealt with as follows:—

| | | | |
|---|---|---|---|
| First Preference Shares— | | | |
| Dividend, 6 months to December 31st, 6s. per share... | £10,368 | 18 | 0 |
| Second Preference Shares— | | | |
| Dividend, 6 months to December 31st, 6s. per share... | 1,400 | 14 | 0 |
| Ordinary Shares— | | | |
| 6d. per share (free of income tax) ..... | 2,208 | 0 | 6 |
| Balance to current half-year's account ... ..... | 1,325 | 11 | 9 |
| | £15,303 | 4 | 3 |

The traffic receipts for the six months show an increase of £1,083. 1s. 3d., compared with the corresponding period of 1894. The expenses of repairing cables amounted to £7,097. 9s. 3d., being £3,403. 13s. 7d. less than for the corresponding period. This decrease is chiefly due to the smaller quantity of cable used, and to the Company's s.s. "Grappler" having been credited with the cost of freight on cable carried out by her to the West Indies in August last. The "Duchess of Marlborough" is still out of commission.

The amount of the subsidies is £1,000 less than in the corresponding period, owing to the termination of the contract with the French colony of Guadeloupe, which formerly paid the Company £2,000 per annum.

Since the close of the half-year, the Directors report that St. Vincent has reduced its subsidy from £600 to £400 for the year commencing April 1st, on the ground of the depressed financial condition of the colony. The telegraphic service of this colony with a subsidy of £600 is carried on at an actual loss of about £1,100 per annum, without counting any interest on capital. The traffic receipts do not meet the office expenses, and even the original subsidy of £800 per annum was quite inadequate to defray the proportionate cost of maintaining the system. This further reduction of the subsidy is considered by the Directors to be most discouraging. The existence of the telegraph at St. Vincent, as well as at several other of the British Colonies served by the Company, is of far more importance to Imperial and Colonial administration than to commercial interests; and the communication having to be maintained at such stations at a loss is a result that could not have been contemplated when the Company was formed.

Mr. William Andrews offers himself for re-election as Director, as do the auditors, Messrs. Deloitte, Dever, Griffiths and Co.

## NEW COMPANIES, STATUTORY RETURNS, &c.

*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1896, pages *318-346, &c., &c.*

**BLACKHEATH AND GREENWICH DISTRICT ELECTRIC LIGHT COMPANY (LIMITED).**—This Company was registered on May 11th with a nominal capital of £5,000, in £1 shares, to apply for, obtain and carry out the terms of a Provisional Electric Lighting Order or Licence, to construct, lay down, establish, fix and carry out all necessary cables, wires, lines, accumulators, lamps and works, to generate, accumulate, distribute and supply electricity, and to carry on the business of an electric light company in all its branches, electricians, mechanical and electrical engineers, suppliers of electricity, and manufacturers of and dealers in all kinds of electrical apparatus. Amongst the first subscribers are: W. Claude Johnson, civil engineer, Charles E. S. Phillips, and Alfred F. Yarrow, each with 100 shares.

**HENRY SMITH AND CO. (KIEFF) (LIMITED).**—This Company was registered on April 29th, with a nominal capital of £50,000, in £10 shares, to acquire the business carried on by Messrs. H. P. Smith, S. Wachtel and E. Agar, at Kieff, Russia, under the style of "Henry Smith and Co.," to carry on the business of manufacturers and importers of, and dealers in engines and machinery, telegraph, telephone and electrical engineers, railway and tramway contractors, &c. The first Directors are H. P. Smith, and S. Wachtel.

**SUSSMANN ELECTRIC MINERS' LAMP COMPANY (LIMITED).**—This Company was registered on May 6th with a capital of £80,000 in 39,250 £7 per Cent. Cumulative Preference, 39,250 Ordinary, and 1,500 Deferred shares, all of £1 each, to enter and carry into effect an agreement with the Electric Exploitation Company (Limited), and also an agreement with the Edison and Swan United Electric Company (Limited), to acquire any patents or rights obtained, or to be obtained, for the United Kingdom for improvements in secondary batteries, and in connection with the manufacture and use of galvanic batteries, miners' and other lamps, electrical apparatus, telegraphs, telephones, electric motors and power supply apparatus, to carry on the business of an electric light and power and telegraph and telephone company in all or any of its branches, and to carry on the business of electricians, electrical and mechanical engineers, chemical engineers, suppliers of electricity, and manufacturers of all kinds of electrical appliances. The first subscribers, with one share each, are: E. Dyke, H. H. Lale, H. A. Grimsdick, M. Frayne, H. Thomas, W. Hutton, J. A. Wilkins and E. Day.

**DOVER ELECTRICITY SUPPLY COMPANY (LIMITED).**—The annual return to March 25th has been filed; 4,680 shares have been taken up out of a capital of £50,000, in £5 shares, and the full amount has been called.

**METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).**—The annual return to April 14th has been filed. The nominal capital is £500,000, divided into 49,900 Ordinary and 100 Founders' shares of £10 each. The whole of these have been taken up, 2,132 have been issued as fully paid, and the full amount has been called on the remaining 47,868.

**PHOSPHOR-BRONZE COMPANY (LIMITED).**—The annual return to April 10th has been filed. The nominal capital is £90,000, in 15,000 Ordinary and 15,000 Preference shares of £3 each; 8,375 of the latter and 7,335 of the former have been taken up, the full amount has been called, and paid.

**ROSE AND BIRD (LIMITED).**—The annual return to May 5th has been filed. The whole nominal capital of £3,000, in 2,000 Ordinary and 1,000 Founders' shares of £1 each, has been taken up. The Founders' shares have been issued as fully paid, and all the Ordinary shares have been paid up.

**ROUND'S ACCUMULATOR COMPANY (LIMITED).**—The statutory return of this Company to January 31st has just been filed; 6,040 shares have been taken up out of a capital of £10,000, in £1 shares, and 6,000 of these have been issued as fully paid; £1 per share has been called on 33 and 5s. per share on the remaining 7 shares.

**WILLANS AND ROBINSON (LIMITED).**—The annual return to April 22nd has been filed. The nominal capital is £300,000, divided into 30,000 £6 per Cent. Cumulative Preference and 30,000 Ordinary shares of £10 each; 22,500 of each class have been taken up, and 14,463 Preference and 14,462 Ordinary have been issued as fully paid. The full amount has been called on the remainder.

## CITY NOTES.

**CAMBRIDGE ELECTRIC SUPPLY COMPANY (LIMITED).**—The total revenue of this Company from the sale of current, meter rents, &c., for the quarter ended March 31st last amounted to £1,828. 9s. 10d., against £1,322. 16s. 9d. in the corresponding quarter of 1895. The number of units sold was 65,425, and there was an equivalent of 15,952 8 c.p. lamps connected to the Company's mains.

**CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).**—Letters of allotment and regret for the recent issue of 12,000 ordinary shares of this Company have been posted.

**CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).**—The traffic returns of this Company for the week ended May 10th were £909, against £832 in the corresponding week of 1895, an increase of £77. The total receipts for the half-year amount to £17,936, against £17,815 for the corresponding period of 1895, an increase of £121.

**COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY (LIMITED).**—From our advertisement columns it will be seen that the Electric and General Investment Company (Limited), of 1 and 2, Great Winchester-street, London, E.C., invite applications on behalf of this Company for 10,000 cumulative Six per Cent. Preference shares of £10 each, at a premium of £2 per share, payable £1 on application, £2 on allotment, £2 on September 1, £2 on November 2, £2 on January 1, 1897, and £3 on March 1, 1897. The Company has an authorised capital of £800,000, divided into 40,000 cumulative Six per Cent. Preference, and 40,000 Ordinary shares of £10 each; 10,000 Preference and 22,475 Ordinary shares have already been subscribed for. The Directors have, in addition, power to issue debentures to the extent of £400,000. The present issue is made in order to provide funds for the further development of the Company's operations, and applications from existing shareholders will be preferentially considered. The Company holds Provisional Orders for the parishes of St. James' and St. John (Clerkenwell) and St. Luke, Middlesex, St. George-the-Martyr, Southwark, and the districts of the Wandsworth and St. Olave District Board of Works (Surrey); and the Company also hold controlling interests in the Bournemouth and District Electric Supply Company, the Dover Electricity Supply Company and the Richmond (Surrey) Electric Light and Power Company (Limited). The full payment of 6 per cent. per annum has been paid on the existing Preference shares for the year 1895, and the Directors consider the earnings during the present year will suffice to pay the dividends on the Preference shares, including the present issue. The subscription lists opened yesterday (Thursday), and will close to day (Friday) at 4 p.m., for both town and country.

**EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).**—The Most Honourable the Marquess of Tweeddale has been appointed Deputy-Chairman of this Company.

**LIVERPOOL OVERHEAD RAILWAY COMPANY.**—The traffic receipts of this railway for the week ended 10th inst. amounted to £1,162. The amount for the corresponding week last year was £1,159.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).**—This Company's traffic receipts for the week ended May 8th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,580.

IN LIQUIDATION.

FOR SALE, BY PRIVATE TREATY.

THE OLD-ESTABLISHED BUSINESS OF MORRIS BROS. (Limited), ELECTRICAL ENGINEERS AND MANUFACTURERS, 52, Great Hampton-street, Birmingham.

For particulars apply to the Liquidator, Mr. E. J. ABBOTT, of Messrs. Abbott, Deeley, Hill and Co., Chartered Accountants, 9, Bennett's-hill, Birmingham.

THE METROPOLITAN ELECTRIC SUPPLY CO., LTD., offer the following

**WESTINGHOUSE ENGINES FOR SALE,**

owing to extensions and increase of H.P. required for larger Units.

All the Engines are in good condition and complete in all respects.

FIVE COMPOUND VERTICAL ENCLOSED ENGINES, each capable of indicating 280 H.P. when running at a speed of 250 revs. per minute, with a boiler pressure of 150 lbs. per square inch.

FIVE COMPOUND VERTICAL ENCLOSED ENGINES, each capable of indicating 250 H.P. when running at 280 revs. per minute, with a boiler pressure of 150 lbs. per square inch.

ONE COMPOUND VERTICAL ENCLOSED ENGINE capable of indicating 85 H.P. when running at a speed of 320 revs. per minute, with a boiler pressure of 150 lbs. per square inch.

The whole of the above Engines are fitted with variable expansion gear controlled by flywheel governors.

Permits to inspect may be obtained by application to the ENGINEER at 17, South-street, Manchester-square, W., who will give any further particulars.

### TENDERS INVITED.

CITY OF LEEDS.

TO ELECTRICAL ENGINEERS, CONTRACTORS AND OTHERS:—

The COUNCIL require TENDERS for an ELECTRICAL INSTALLATION sufficient for the working by the overhead system of haulage, a double track of Tramway seven miles long. The work will be divided into the following Contracts:—

1. POLES for supporting Trolley Wire.
2. UNDERGROUND CONDUITS and CONDUCTORS.
3. TROLLEY WIRE and attachments.
4. MOTOR CARS.
5. ACCUMULATORS and SWITCHES.
6. STEAM ENGINES.
7. DYNAMOS, SWITCHBOARDS and ACCESSORIES.

Tenders endorsed with the number of the contract must be sent in, addressed to the Town Clerk, Town Hall, Leeds, not later than JUNE 20th next.

Particulars, plans and forms of Tender may be had (on payment of a deposit of £2 2s. for each contract, which will be returned on receipt of a bonâ fide Tender) from the City Engineer, Municipal Buildings, Leeds, or from

Dr. JOHN HOPKINSON, F.R.S., 5, Victoria-street, Westminster, S.W.

### APPOINTMENTS VACANT.

CITY OF LINCOLN.

PUBLIC HEALTH ACT, 1875.

TO ELECTRICAL ENGINEERS.

THE CORPORATION OF LINCOLN (who are intending to construct Works for the supply of Electricity in Lincoln) invite applications for the appointment of ELECTRICAL ENGINEER.

Candidates must have had previous experience in a similar appointment with a Company or Corporation supplying electricity under Parliamentary powers and be competent to design and supervise the construction of the generating station, plant, machinery, cables and appliances necessary to generate and supply electricity for public and private lighting on the low tension direct current system. The Engineer appointed will be required to devote his whole time to the service of the Corporation.

The salary will be at the rate of £300 per annum.

Particulars of Duties, &c., and Forms upon which applications must be made may be obtained from the undersigned, to whom applications (endorsed "Electrical Engineer") must be sent not later than Saturday, the 6th day of June, 1896.

Canvassing members of the Council will disqualify a candidate.

St. Peter's Churchyard, Silver-street, Lincoln, 18th May, 1896.

H. K. HEBB, Clerk of the Urban Sanitary Authority and Deputy Town Clerk.

COUNTY BOROUGH OF SALFORD.

MUNICIPAL TECHNICAL INSTITUTE.

The following APPOINTMENTS are about to be made, viz.:—

CHIEF LECTURER in CHEMISTRY, salary £200.

CHIEF LECTURER in DYEING, salary £150.

ART MASTER, salary £220.

Forms of application and particulars of duties may be obtained upon application to the SECRETARY at the Institute, Peel Park, Salford.

By order,

SAML. BROWN, Town Clerk.

Town Hall, Salford, 6th May, 1896.

COUNTY BOROUGH OF SALFORD.

MUNICIPAL TECHNICAL INSTITUTE.

WANTED an INSTRUMENT MAKER, wages £2 per week. Forms of application and particulars of duties, &c., may be obtained from the SECRETARY at the Institute, Peel Park, Salford.

By order,

SAML. BROWN, Town Clerk.

Town Hall, Salford, May 6, 1896.

NORTHERN POLYTECHNIC INSTITUTE.

THE GOVERNORS invite APPLICATIONS for the appointment of HEAD of the DEPARTMENT of PHYSICS and ELECTRICAL ENGINEERING; commencing salary £250 per annum.

The appointment will date from September 29th, 1896, but the candidate appointed will be expected in the meantime to consult with the Principal as to the equipment and organisation of the Department.

Conditions of appointment, and forms of application, may be obtained from the Secretary, at the Institute, Holloway-road, London, N.

Applications, accompanied by copies of recent testimonials and the names of three referees, to be sent in to the PRINCIPAL, not later than June 1st, 1896.

E. GRIFFITHS, Secretary.

ELECTRICIANS.—NOTICE to EMPLOYERS.—Please note we have a number of First-Class ELECTRICAL MEN upon our Books. Kindly send us particulars of any VACANCIES you may have. We can introduce you, free of charge, to the best men now at liberty.

Address, CHAS. RICHARDSON and CO., Engineers' Bureau 342, Strand, London, W.C

PARTNERSHIPS.—ELECTRICAL ENGINEERS and others WANTING PARTNERS, or wishing to SELL, can be introduced to Clients with Capital; and GENTLEMEN Seeking Investments can obtain personally (or through their solicitors) particulars of bona-fide OPENINGS. Strictest confidence observed.—Address, CHAS. RICHARDSON and CO., 342, Strand, London, W.C.

WANTED, LAMP TOPS with Platinum, Scrap Platinum, &c.—EDEY and Co., 256, Ferndale-road, Brixton, S.W.

PLATINUM UTENSILS, SCRAP, LAMP TOPS.—Best prices given by Derby and Co., 44, Clerkenwell-road, London, E.C. N.B.—Platinum sold

FOR SALE CHEAP.—Quantity of new and second-hand TELEGRAPH and ELECTRICAL APPARATUS, including Wheatstone perforators, keys, sounders, lineman's galvos., also pair floating compasses in oak cases, and small medical coil.—1, Talma-road, Brixton, S.W.

HORSELESS CARRIAGES.—Messrs. E. H. CADIOT & CO., 12, Rue St. Georges Paris, solicit correspondence on the subject of Horseless Carriages, and are buyers of SMALL OIL ENGINES, from ¼ to 4-H.P.

ACCUMULATOR CHARGING.—C. H. CATHCART and CO., having plant specially adapted for this purpose, Charge Cells of all sizes promptly, thoroughly and cheaply. Terms on application. Accumulators on Hire for temporary lighting, experimental uses, &c.—3, Dorset-buildings, Salisbury-square, Fleet-street, E.C. (Telephone No. 65,266.)

## CITY AND GUILDS OF LONDON INSTITUTE,

SESSION 1896-97.

THE COURSES OF INSTRUCTION IN ENGINEERING AND CHEMISTRY at the Institute's Colleges commence in October, and cover a period of two to three years. The MATRICULATION EXAMINATION of the **Central Technical College** will be held on September 21st to 24th and the ENTRANCE EXAMINATION of the Day Department of the **Technical College, Finsbury**, on September 22nd.

**CITY AND GUILDS CENTRAL TECHNICAL COLLEGE**

(Exhibition-road, S.W.), a College for Higher Technical Instruction for Students not under 16 years of age preparing to become Civil, Mechanical or Electrical Engineers, Chemical and other Manufacturers, and Teachers.

THE MATRICULATION EXAMINATION will be held on September 21st to 24th, and the new Session will commence on October 1st.

Professors:—O. Henrici, LL.D., F.R.S. (Mathematics); W. C. Unwin, F.R.S., M.I.C.E. (Civil and Mechanical Engineering); W. E. Ayrton, F.R.S. (Physics and Electrical Engineering); H. E. Armstrong, Ph.D., F.R.S. (Chemistry).

**CITY AND GUILDS TECHNICAL COLLEGE, FINSBURY**

(Leonard-street, City-road, E.C.). The DAY DEPARTMENT provides Courses of Intermediate Instruction for Students not under 14 years of age, preparing to enter Mechanical or Electrical Engineering and Chemical Industries.

THE ENTRANCE EXAMINATION will be held on September 22nd, and the new Session will commence on October 6th.

Professors:—S. P. Thompson, D.Sc., F.R.S. (Electrical Engineering); J. Perry, D.Sc., F.R.S. (Mechanical Engineering); R. Meldola, F.R.S. (Chemistry).

JOHN WATNEY, Hon. Secretary.

## ABRIDGED PROSPECTUS.

In the year 1888, a Syndicate was formed for the purpose of thoroughly testing Mr. Radcliffe Ward's System of Electric Street Traction, and after years of successful investigation and experimental work, it has been decided to form a Company with Working Capital adequate to the introduction of the system in London and elsewhere.

A highly satisfactory report has just been received by the Directors on the novelty, validity, and utility of the Patents, made by Mr. John Imray, the well-known Patent expert of the firm of Messrs. Abel and Imray.

This Company has obtained the exclusive licence for Omnibuses and Stage Carriages generally, as well as Cabs, in England. The estimate of the financial results that will attend its adoption have been arrived at after careful calculation and investigation.

Numerous runs have been made under the most arduous conditions as to snow, greasy mud, &c., which have completely attested the capabilities of Electricity under adverse conditions. Minute measurements have been made of the electric power needed under every condition, and full data as to all the requirements of such a vehicle for the first time obtained.

The result is the system now introduced to the public.

Without going into scientific detail, it may be shortly explained that one of the features of the Ward system enables an Electric Car to start or run up hill without increase in the rate of discharge of the electric current from the Accumulators, hitherto a cause of enormous expense and waste in working Accumulator traction. That result is obtained in an extremely efficient way, operated by the Omnibus driver without any additional complication—a most important feature where the driver himself steers his vehicle through the traffic.

Mr. Ward's great and unique experience in this branch of engineering gives him an exceptionally advantageous position, and the Directors are satisfied that the system embodied in the patents is one which will ensure the success of his Company.

The following figures, extracted from the Balance-sheet of the London General Omnibus Company, show the traction cost of 911 omnibuses for 6 months—10,693,359 miles—the actual number of miles run.

| | £ | s. | d. |
|---|---|---|---|
| Horsekeeper's wages and yard expenses | 42,367 | 14 | 7 |
| Horse stock, less sales and carcases | 48,826 | 10 | 3 |
| *Maintenance.* | | | |
| Food | 119,016 | 0 | 6 |
| Bedding, shoeing, and Veterinary service | 14,804 | 17 | 9 |
| *General.* | | | |
| Harness, stable expenses, &c. | 12,209 | 14 | 10 |
| Total | £237,224 | 17 | 11 |

Dividing £237,224. 17s. 11d. by 10,693,359 miles, equals 5·32 pence per omnibus per mile.

This is exclusive of drivers and conductors, office expenses, and general administration.

Digitized by Google

# THE LONDON ELECTRIC OMNIBUS COMPANY, LIMITED.—*Continued.*

The following figures are based on the actual results obtained during the running of the electric omnibus 5,000 miles through the traffic of London streets.

COST OF RUNNING 911 ELECTRIC OMNIBUSES FOR SIX MONTHS—13,264,160 MILES.

| | £ | s. | d. |
|---|---|---|---|
| Fuel, Oil, and Stores | 24,633 | 8 | 9 |
| Motive Power, wages, engine-drivers, stokers, &c. | 6,632 | 1 | 7 |
| Maintenance of Station plant, repairs, &c. | 14,093 | 15 | 6 |
| Maintenance of accumulators, motors, and gear | 60,794 | 1 | 4 |
| Station superintendence | 17,286 | 18 | 6 |
| Car sundries | 11,827 | 4 | 2 |
| Total | £135,267 | 9 | 10 |

Dividing £135,267 9s. 10d. by 13,264,160 miles (one of the advantages of the Electric Omnibus is that it runs a greater number of miles in the same working hours), equals 2·44 pence per Omnibus per mile.

This is exclusive of drivers and conductors, office expenses, and general administration.

The published accounts of the London General Omnibus Company, from their balance sheet of the 31st December, 1894, show an available profit for six months on the running of 911 Omnibuses sufficient to pay £75 clear profit per 'bus per annum.

The saving effected by the Electric System is the difference between 5·32 pence per Omnibus per mile, cost of horse traction, and 2·44 pence per Omnibus per mile, the cost of this Company's traction. Therefore, a saving is effected of 2·88 pence per Omnibus per mile on each Omnibus of the Company, irrespective of the number of Omnibuses run.

The working capital allowed for in this Company is sufficient to provide for 125 Omnibuses, running 70,000 miles per week. Ignoring what may be called the ordinary profit of £75 per 'bus per annum, as shown above, and taking only the saving, the 2·88 pence multiplied by 70,000 miles per week, multiplied again by 52 weeks, equals £43,680, sufficient to pay a handsome dividend on the Company's capital of £250,000.

The dividend-earning prospects of this Company are enhanced by the fact that it is intended to form subsidiary companies for provincial towns, in which this, as the parent company for England, will retain valuable interests.

The President of the Local Government Board (the Rt. Hon. H. Chaplin, M.P.) announced some time ago that the Government intended to bring in a Bill for removing the existing restrictions for the running of Horseless Vehicles on the roads and streets. This has now been done. The Company will set to work immediately after allotment in building the Ward Omnibuses, so as to be ready for traffic as soon as the Act is passed.

The Directors, while perfectly free to use the best Accumulator to be obtained in the open market, have secured on favourable terms for this Company the use of a new Electric Accumulator the size and weight of which are considerably less than those hitherto in ordinary use, without any sacrifice of efficiency; whilst it has other additional advantages, such as reduced cost of manufacture.

The following contracts have been entered into (1) dated the 19th May, 1896, between Mr. Radcliffe Ward and the Company, under which the Company acquires an exclusive licence for England for the patents set out in the Schedule at the price of £100,000, of which £20,000 will be paid in cash, and the balance will be satisfied in fully paid shares, which will not participate in dividends until after sufficient profits have been earned to pay, in any one year, a dividend of 7 per cent. upon the remainder of the Shares; (2) dated the 19th May, 1896, and made between The Sola Accumulator Company and this Company; granting them the sole monopoly for omnibuses and cabs for London.

The Vendor under the former Contract, who is the promotor of the Company, has fixed the purchase money to be paid by the Company as above-mentioned, and agrees to pay all printing, advertising, and other preliminary expenses attending the incorporation and formation of the Company up to allotment. During his negotiations for the formation of the Company Agreements have been entered into with various parties in connection therewith, and as to the above expenses and the issue of the capital now offered, and with persons interested in the purchase money, to none of which the Company is a party. Applicants for shares must be deemed to have had notice of these agreements, and to have waived all right to any particulars thereof, whether under Section 38 of the Companies Act, 1867, or otherwise.

The Memorandum and Articles of Association, with copies of the above-mentioned Contracts, may be seen at the offices of the Solicitors of the Company.

Applications for Shares may be made on the accompanying form, and forwarded to the Bankers of the Company with the amount of the deposit. If no allotment is made, the deposit will be returned in full, and where the number of shares allotted is less than that applied for, the balance will be applied towards the payment due on allotment, and any excess returned to the applicant.

Mr. William Marshall and Mr. Radcliffe Ward, Directors of the Company, are the Vendors.

Prospectuses and Forms of Application for shares can be obtained from the Bankers, Solicitors, and Brokers, and at the offices of the Company.

*London, 19th May*, 1896.

## REPORT ON THE SYSTEM OF THE

# LONDON ELECTRIC OMNIBUS COMPANY, LIMITED,

### By CHARLES E. SPAGNOLETTI, Esq., M.I.C.E.,

**Past Pres. Inst. Electrical Engineers; Consulting Engineer to the Great Western Railway, Metropolitan Railway; and Consulting Electrical Engineer, City and South London Electric Railway during construction.**

To the Directors of

THE LONDON ELECTRIC OMNIBUS COMPANY, LIMITED,

(WARD'S SYSTEM).

GENTLEMEN,

There can be no doubt that the next few years will bring about a total change in the system and means of conveyance at present in use, and electricity will play a very prominent part in this change. There is no science in which improvements have been so rapidly developed as in that of electricity, and the continued advances now being made tend to cheapen and, in every possible way, extend its use.

It has already shown its commercial adaptability for traction purposes in Electrical Tramways and Electrical Railways, and the extension of these now being made is an additional proof of its value for such purposes.

From the results of Mr. Radcliffe Ward's long experience and practical work, I consider there is every prospect of success for your Company. There can be no doubt that for street traffic, Electricity possesses many and great advantages over other systems. It is free from smell of oil vapour, heat and explosions; is silent, clean, and easily worked and controlled.

Horseless Vehicles on this system will afford great advantages, inasmuch as they will take up less space, can turn in less space, and can be stopped and started very quickly.

There will be less pollution in the streets, which in hot weather are at times most offensive owing to vapour and dust, and I believe are responsible for much sickness. They will avoid the cruel strain put on horses in starting vehicles to which they are attached, particularly on wood and asphalt pavements when wetted by rain or watering, and the rapid introduction of such a system is very greatly to be desired.

The less the number of horses, the greater will be the mitigation of the present evil.

I find that Mr. Ward's recent improvements include details which, in my opinion, will greatly add to the comfort of passengers, economy in the cost of maintaining the vehicles, and to the life of the Accumulators used for such purposes.

The system of gearing the motors to the axles I believe is novel, and will prove efficient and economical.

I may state in conclusion that I have been induced to accept the position of Consulting Electrical Engineer in your Company, as I strongly believe in the future success of the undertaking.

I am, yours, &c.,

(Signed)

*London, 16th May*, 1896. CHARLES E. SPAGNOLETTI.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 940. [Vol. No. 4. XXXVII.] FRIDAY, MAY 22, 1896. PRICE SIXPENCE.

## NOTES.

As we go to press the announcement reaches us that a Special General Meeting of the members only of the Institution of Electrical Engineers will be held on Friday next, the 29th inst., at 4 p.m., at the offices of the Institution. This meeting has been summoned "for the purpose of considering and, if approved, passing resolutions altering the regulations contained in the Articles of Association of the Institution (in order that such resolutions, if confirmed by a subsequent meeting, may become Special Resolutions)." A copy of the proposed resolutions is before us, and we hope to publish these in our next issue.

During the past week the investing public has been asked to subscribe to two concerns, with an aggregate authorised capital of £1,000,000 sterling, the objects of both being the promotion of the mechanically and electrically propelled vehicle industry. The larger of these concerns, calling itself "The Great Horseless Carriage Company," has a capital of £750,000, of which one-third is for working capital; while the smaller, styled "The London Electric Omnibus Company," contemplates an issue of 170,000 shares, the vendor patentee, Mr. Radcliffe Ward, receiving £100,000, of which £20,000 only is in cash, for the sale of his rights in the electric omnibus he has been pioneering. There is an unmistakable inclination on the part of investors, at the present moment, to put their money in large, not to say altogether huge, amounts into concerns relating to the manufacture of cycles and other horseless vehicles, and it would not surprise us to hear that either or both of these two concerns had been able to go to allotment. At the same time it will probably occur to those who are acquainted with the present development of horseless carriage traffic, that the Bill rendering such traffic legal in public thoroughfares has not yet become law; and, further, that it would be extremely curious and inexplicable if electric accumulator omnibuses running on ordinary roads could be made to pay, while electric accumulator cars running on tramrails apparently cannot. It naturally strikes us as being easier to make a success of any system of mechanical traction on the smooth track of a tramway than on the uncertain and more difficult common road. But, the commercially successful accumulator tramcar—where is it?

Considerable interest attaches to the statement of accounts f the Belfast electric supply concern, just published for the year ended December 31, 1895. In a recent issue we announced that the Belfast municipal authorities had decided not to proceed with their original scheme of building a number of gas engine sub-stations, fed from the municipal gas works, but were about to erect a large steam station; and we remarked that the absence of particulars as to the working expenses of the Belfast system prevented us from drawing any final conclusions about the matter. Now, however, we are in possession of data which makes possible an accurate comparison between the gas-driven station and other stations.

A total of 95,126 units have been generated, with a total consumption of 4,454,667 cubic ft. of fuel gas from the town mains, or 46·8 cubic ft. per unit generated. The price paid for gas was 2s. 3d. per 1,000 cubic ft., or 1·26d. per unit generated. Of the total amount generated in the year, 82,197 units have been sold during the hours when the charge has been 7d. per unit, and 574 units in the time when 4d. per unit was charged. The units sold, therefore, have amounted to 87 per cent.; and if we deduct from the remainder the 3,822 units used on the works for lighting, starting the engines, &c., the residue represents a loss of only 9 per cent. of the total energy generated. The energy wasted in the batteries has been 6,304 units, and in the mains 2,229 units, figures which correspond respectively to 6·7 per cent. and 2·3 per cent. of the total generated. Accordingly, the consumption of fuel gas per unit sold has been 53·7 cubic ft., the cost of which has been 1·45d.

It has been alleged against gas engines that their consumption of lubricating oil is a more serious item than with steam engines of equal size. The total cost of lubricating oil, waste, circulating water and stores, at Belfast, has been £80. 4s. 3d., or 0·202d. per unit generated, or 0·232d. per unit sold. It cannot be alleged that either of these figures is excessive. Higher figures are often reached in steam-driven stations. In fact, the total generating expenses have not exceeded 2·82d. per unit generated, or 3·24d. per unit sold, figures which are not unreasonably large for a station of the size of that at Belfast. Finally, as regards a comparison of capital costs of generating machinery, the Belfast generating plant cost £15. 7s. per kilowatt, or 13s. 1½d. per 8 c p. lamp capacity. These figures are well below the average, and tend to show that the capital cost of a gas-driven station need not exceed that of one of equal capacity driven by steam.

Digitized by Google

One practical result, if not more than one, has followed the reading of Capt. H. Riall Sankey's Paper on "The Thermal Efficiency of Steam Engines," a short abstract of which appeared in *The Electrician*, Vol. XXXVI., p. 796, for the Council of the Institution of Civil Engineers has appointed a committee, to consider the question of arriving at a definition of a standard or standards of thermal efficiency for steam engines. This committee will include Capt. Sankey, together with Profs. A. B. W. Kennedy, T. H. Beare, J. A. Ewing, and Messrs. Bryan Donkin, Macfarlane Gray, M. Longridge and W. H. Maw. Modern steam-engine theorists have on several occasions evinced dissatisfaction with the old-fashioned standard of efficiency afforded by the Carnot cycle. And even the less ancient cycle used by Clausius in his steam engine researches has been voted unsuited to modern requirements. It will be remembered that the main purpose Capt. Sankey had in view, in bringing his Paper before the Civil Engineers, was to present for discussion an ingenious modification of the Clausius standard, which would answer the purpose of the practical theorist, if we may coin the phrase. Doubtless our readers will also remember that in his recent "James Forrest" lecture, which we reprinted and commented upon last week, Prof. Kennedy stated that he does not in the least share "that great objection to the Carnot cycle which I know fills the breasts of some of my friends." We may look upon Prof. Kennedy as filling his place on the committee as counsel for Carnot and the *status quo ante*.

The first and most obvious thing which any committee would have to do that set itself to evolve a standard of steam-engine efficiency, would be to decide which are the unavoidable and which the merely contingent or avoidable losses in the steam engine. A list might be drawn up of all the items of possible loss of energy in steam engines, and these should be classified under the two heads indicated. Whatever mechanism, imaginary or real, was selected for the standard engine, it should comply with the condition that it should divide between the avoidable and the unavoidable losses. When, indeed, we are comparing any heat engine with a non-heat engine, it is quite fair to debit the former with the unavoidable as well as the avoidable losses. But when it is a case of comparing steam engines, or any other kind of heat engines, among themselves, a standard may reasonably be selected that will hold a just balance between what is actually done and what might really and actually have been done. The inevitably necessary losses in such a case should be put out of court.

The Paper on "Steel Steam Pipes and Fittings," which was read by Mr. Samuel McCarthy before the Institution of Mechanical Engineers at the beginning of this month, and which we commence to reprint this week, is in many ways interesting to electrical engineers. To begin with, it gives some account of the Benardos process of electric welding as applied to the welding of steam flanges, joints, &c. Several electric supply stations in this country are fitted with steam and exhaust mains which have been welded at the flanges and joints in this manner. The author of the Paper, who is connected with the electric welding department at Messrs. Lloyd and Lloyd's works, brings a great deal of technical experience in this matter to bear upon his subject. But, apart from the electrical side of this Paper, there is much useful information regarding the use of steam pipes that should be welcomed by central station engineers. Some of the most serious difficulties in practice arise from the faulty and uneconomical design or the unskilful use of steam mains. It is only quite recently that at a meeting of the Northern Society of Electrical Engineers several central station engineers complained that it was impossible to shut down their steam mains in the daytime, since the joints failed when steam was turned on if they did so. The practice of keeping the entire system of mains under steam all day long is a terribly expensive evil. It may be a necessary evil at the present time, but it may be well to take to heart the advice of Mr. Fawcus, to learn as quickly as possible how to be able to shut down the steam mains daily without risk. There is a fortune for the inventor of a pipe joint that will withstand the great stresses arising from the change in temperature.

To return to electric welding. The practice adopted by Messrs. Lloyd and Lloyd and, we infer from the Paper, by other pipe makers, is to gas or roll weld the longitudinal seams, and to use the electric process only for the flanges and circumferential joints. Electric welding is too expensive for the seams, we are told, though it is not too costly to enable it to compete with other processes as regards the other work. This limitation is to be regretted, since it entails the use of two or even three different kinds of welding apparatus at the same works. Nor do we believe that the limitation arises from anything but a failure to properly adapt the electric process to the different kind of operation which longitudinal seam welding entails. It can hardly be that there are such inherent difficulties in electric seam welding that competition with gas welding is altogether out of the question. When effectively done, electric welding makes a joint which is as tough, elastic and strong as the solid metal, and should place tubes on an equal footing with the excellent, though rather costly, seamless tubes so much admired by Mr. Platt.

No one will grudge the birthday honours bestowed upon so distinguished an explorer as Sir Clements Markham, so accomplished an educationist as Sir Joshua Fitch, or so renowned an astronomer as Sir David Gill; their names illuminate the otherwise dreary list of politicians, colonial judges and heroes (military or naval) who figure along with the successful contractor and the plodding civil servant. But where are the honours bestowed either on art or on science? We have lately seen honours and decorations—including the dignity of baron—bestowed upon Prof. Röntgen. Let us rejoice at the enlightenment of foreign governments. But why does our own British Government ignore the merits of the man without whom Röntgen would never have made his discovery? The inventor of the radiometer, the discoverer of thallium, the pioneer in spectroscopy, the patient investigator of the phenomena of high vacua—Mr. Crookes, has done more for science than most men of his generation. It is certainly

Digitized by Google

strange, too, that the inventor of the printing telegraph and of the microphone, whose work has been recognised by so many foreign governments, should also remain without recognition in his native land. But prophets always were without honour(s) in their own country.

**Sir John Pender.**—Sir John Pender's health continues to show some improvement. He was able to walk out, and also to take carriage exercise in the early part of this week.

**New Use for Carborundum.**—It is reported that a new use for carborundum is found in the manufacture of filaments for incandescent lamps.

**A Large Gas Engine.**—The Paris Otto Gas Engine Company, says the *Gas World*, is getting a 1,000 H.P. gas engine ready for the next Exhibition (1900). Fuel gas will be used

**The Kelvin Jubilee.**—Prof. Sir G. G. Stokes, Prof. A. R. Forsyth, and Prof. J. J. Thomson are, says *Nature*, to represent Cambridge University at the celebration in Glasgow of Lord Kelvin's jubilee next month.

**The Wiring Question.**—On Wednesday, May 27th, at 8 p.m., Mr. Frederick Bathurst will lecture to the Electrical Trades Union at the Club Union Buildings, Clerkenwell-road, E.C., on "The Wiring Question."

**Obituary.**—We have to announce the death, at the early age of 27 years, of William Horace Cadiot, son of Mr. E. H. Cadiot, of Paris. Mr. Cadiot was electrical engineer at the electricity station of Jacmel (Hayti).

**The Toronto Meeting of the British Association.**—The Council of the British Association have resolved to nominate Sir John Evans, K.C.B., Treasurer of the Royal Society, for the presidency at the meeting which will be held next year in Toronto.

**The Dublin-Dalkey Tramway.**—On Saturday last the electric tramway from Dublin to Dalkey was formally inaugurated. Cars have been running over portions of this line for some time past. A full illustrated description of this interesting tramway system appeared in *The Electrician*, Vol. XXXVI., page 382.

**Cable Interruptions and Repair :—**

**Fatal Accident at Bedford Electric Supply Station.**—On Friday last, at one of the sub-stations of the Bedford electric supply system, a young mechanic, while engaged in removing a fuse-box from a transformer, received a shock and was killed on the spot. Another labourer, who assisted, was also knocked down, but recovered shortly afterwards. The system employed at Bedford is high-tension alternate current at 2,000 volts, with transformer sub-stations. At the inquest it was stated that a Board of Trade inquiry would be held.

**A Monster Belt.**—What is stated to be the largest belt ever made in America is in process of manufacture at the Chicago Belting Company's works. The dimensions of the completed belt are as follows :—Length, 150ft.; width, 7ft.; weight, 30cwt.; thickness, $\frac{7}{8}$in. In its construction the selected portions of 450 oak-tanned hides, picked from over 5,000 skins, were used. The destination of this belt is the engine room of the Louisiana Electric Light Company at New Orleans, where it will be attached to the 28ft. driving wheel of the great Allis-Corliss engine.

**Royal Society.**—At the meeting of the Royal Society yesterday the following Papers were down for reading :—"On the Changes Produced in Magnetised Iron and Steel by cooling the Temperature of Liquid Air," by Prof. J. Dewar, F.R.S., and Dr. J. A. Fleming, F.R.S.; "Helium and Argon, Part III., Experiments which have yielded Negative Results," by Prof. Ramsay, F.R.S., and Dr. Collie, and "On the Amount of Argon and Helium contained in the Gas from the Bath Springs," by Lord Rayleigh, Sec. R.S.

**Electric Lighting in Theatres.**—The first of a series of three volumes has recently been issued of a work on "Modern Opera Houses and Theatres," by Edwin O. Sachs and E. A. E. Woodrow. This treatise comprises a large number of examples selected from European theatres, with reference to design and construction, and with supplementary sections dealing with the *technique* of theatre lighting, danger from fires and protective legislation. The first volume contains some hundred large and artistically-drawn plates, and the complete work will comprise 220 plates. The plans and detailed drawings are made to a uniform set of scales.

**Electrical Communication with Lighthouses.**—In consequence of difficulties which are still encountered, in certain circumstances, in maintaining electrical communication with light vessels, the Royal Commission on Electrical Communication with Lighthouses and Light Vessels have decided to postpone publication of their final report. An interim report has just been issued, in which the Commissioners state that, so far as lighthouses are concerned, the cables laid on their recommendation have worked satisfactorily, while as regards the cables to light vessels the results have been disappointing. Experiments are being undertaken to remove the causes of failure.

**Errata.**—In Mr. F. C. Raphael's article on "The Localisation of Faults in Electric Mains," on page 71, column 2, line 10 from the bottom, *et seq.*, for "the fault resistance of the negative main is 5,000 ohms, and that of the *negative* main is high in comparison," read "the fault resistance of the negative main is 5,000 ohms, and that of the *positive* main is high in comparison."—In the report in our last issue of the Paper of "The True Resistance of the Electric Arc," read before the Physical Society by Messrs. Frith and Rodgers, and in column 2, line 42 from top, for "between 75 and 0" read "between 7·5 and 0." As a matter of fact, the critical frequency at which the resistance of the arc changes sign was stated by the authors to be, from *à priori* reasons, between 7·5 and 0, and was actually found by them to be 1·8 $\sim$ per second.

**The City and South London Railway.**—The Bill promoted to extend the time for the purchase of lands for the purposes of the City and South London Railway Act, 1893, and for the completion of the underground railway and other objects, came before a Select Committee of the House of Commons on Monday last. The main question before the Committee was the demolition of the Church of St. Mary Woolnoth, in King William-street, for the purpose of erecting a station. Mr. C. G. Mott, Chairman of the Company, said the church was not wanted. There were ten churches within a radius of 200 or 300 yards, two of them being actually in the same street as St. Mary's. Besides, St. Mary's had no congregation, and there were no peculiar associations connected with it. The Committee found the preamble of the Bill proved, subject to the insertion of a clause for the protection of St. Mary Woolnoth, and declaring that it shall be referred to the arbitrator to take into consideration the additional liability which will devolve on the Company in consequence of giving up their present rights.

**Applied Electro-Chemistry.**—Mr. Swinburne gave his fourth and last Cantor lecture on Monday last. The lecture was devoted to experiments on electric furnaces. Aluminium bronze was made before the audience by the Cowles process on a small scale. Calcium carbide was also made in a small furnace, and a little generator was shown giving off acetylene from the carbide and feeding a 40-candle burner. Furnaces were also shown in action reducing uranium oxide and fusing tungsten, which is an exceedingly refractory metal. Zirconia and lime were melted in small quantities by maintaining a current through them. A piece of carbon pencil is used to start the experiment, and when it is burned off the heated oxide and hot air carry the current, of course offering considerable resistance and generating great heat. The manufacture of phosphorus in the lecture room by means of the Readman process would have been odorous if the room had not been already reeking with acetylene. The lectures will be published in the Society of Arts *Journal* during the summer.

**Burn-Out of Mains at Charing Cross.**—We happened to pass along Northumberland-avenue on Monday morning last, at about 9.30, when we noticed smoke escaping from some of the mid-road and side manholes. A fire engine was on the spot, and it soon became evident that the electric light and other cables in the spacious subway beneath the centre of the road were on fire. There have been already, we understand, two fires of a non-electrical nature in that subway; and, so far as we have been able to ascertain, there is nothing to show that the direct cause of Monday's fire was electrical. Whatever the cause damage was done to, and temporary interruption caused in, the cables of the Metropolitan Electric Supply Company, the Charing Cross and Strand Electricity Supply Corporation, the Post Office telegraphs and the telegraph wires of the District Messenger Company. There was no interruption of traffic, and the consequences of the outbreak were of a less serious nature than might have been expected from the smoke produced.

**Soda and Potash Works at Niagara.**—It is announced in the American technical press that the Walton Ferguson Chemical Company's plant at Niagara Falls will shortly be started. This plant is the latest one built on the land of the Niagara Falls Power Company. At present it consists of two buildings, one of which is 60 × 125ft., and the other 30 × 60ft. Both are two stories high and built of wood. This company will manufacture potash and soda electrically. All the electrical appliances, transformers, &c., will be located in the smaller building, while on the upper floor of the larger buildings will be placed the large porcelain-lined iron tanks designed to contain the crude material for the manufacture of potash and soda. These tanks will be about 100 in number. When the plant begins its work it will consume about 1,000 H.P. One ton a day will be the capacity of the present plant, and the rock salt for making soda will be obtained in Syracuse. From Germany will come the crude material for making potash. As yet the subway in which the cables carrying power to the aluminium and carborundum works have not been extended so far as the carbide or soda plants, but they soon will be, and until they are, the power will be conducted by cables carried above ground.

**Conversion of Emery into Corundum.**—An electric process of converting emery into corundum by means of the alternate-current arc has recently been patented, says the *Trade Journal Review*. As heat, and not decomposition, is aimed at, continuous currents would be unsuitable. The furnace is made of firebricks and stands on two bridges; the hollow underneath serves as receptacle for the fused mass, there being a small hole in the bottom of the furnace. This hole is covered with a glass plate. The electrodes (carbon rods) are approached to within 1in. to 2in., the space between being packed with lumps of carbon. The emery, the finest dust, of little use otherwise, is mixed with powdered coal, the amount depending upon the iron oxide in the emery; for 25 per cent. of oxide 5 per cent. of carbon is reckoned. The coal is soon burned by the oxygen of the iron oxide and the arc forms. The inner mass begins to melt, the glass plate gives way and a stream of fused corundum flows out. The hard outer crust is then broken with iron rods, and new material thus fed to the arc. This addition stops the flow, which starts again after 10 or 15 minutes. The baseplate is strewn with fine emery powder to protect it from the intense heat of the fused mass. The resulting corundum is almost free of water, of which the emery contains about 5 per cent.

**Convention of the Municipal Electrical Association.**—The following arrangements have been made for the first annual convention of the Municipal Electrical Association, which is to be held in London on June 10th, 11th, and 12th. The meetings will be held at the Royal United Service Institution, Whitehall. At the first meeting Mr. Arthur Wright will read his presidential address on "The Municipal Electrical Association and its Objects," and the following papers, by municipal electrical engineers, will be taken for discussion:—(1) "Electricity Supply at 220 Volts," by A. S. Barnard, of Hull; (2) "Alternating-Current Stations and High-Voltage Lamps," by Harold W. Couzens, of Taunton; (3) "The Control by Municipal Authorities of Consuming Devices and the Wiring Connecting them to the Mains," by C. H. Wordingham, of Manchester; (4) "Electricity Works Records," by A. B. Mountain, of Huddersfield. At the second meeting the following Papers will be taken:—(1) "The Cost of Electricity Supply," by Arthur Wright, of Brighton; (2) "Cable Specifications and Tests," by Joseph A. Jeckell, of South Shields; (3) "The Organisation of an Electricity Works Staff," by E. T. Ruthven-Murray, of Worcester. Mr. John Hesketh's Paper on "Electric Lighting and Traction" will be taken on the afternoon of the second day. At a meeting to be held in Brighton on the afternoon of the third day of the session, a Paper on "Extensions to Outlying Districts" will be read by A. H. Gibbings, of Bradford.

**Belgian Electrical Engineering.**—At the meeting of the Institution of Junior Engineers, on Friday, May 8th, "Notes on Belgian Electrical Engineering Practice" were read by Mr. A. Anstruther-Thomson and Mr. G. C. Allingham. The communication embodied particulars which had been collected by the authors during the Institution's summer meeting of last year. Belgian electrical practice was difficult to define exactly. It was usual to associate English practice with high-speed engines, direct-coupled to dynamos or alternators, and Continental with slow-speed engines driving multipolar dynamos; no rigid distinction existed, however. Belgian practice seemed strongly influenced by both the foregoing characteristics, and was, therefore, extremely interesting as showing a variety of types, and affording exceptional opportunities for comparison. The system of free publication of central station accounts to which in this country we were accustomed was not adopted in Belgium. Originally high-speed dynamos were driven from slow-speed engines by belts; to secure the advantages of direct-coupling, in England the engine speed was increased, whilst on the Continent the dynamo speed was diminished. After briefly touching on the term "load-factor," and its influence on central station practice, the preference shown on the Continent for continuous current and large batteries was pointed out. With regard to electricity for power purposes, there were no long-distance transmissions in Belgium, and hardly any multiphase plant, but the use of electromotors in workshops was steadily increasing. Several instances were given, notably the important installation at the Herstal Small Arms Factory. General conclusions appeared to show that in electrical practice Belgium occupied a position intermediate between England and the Continent.

**The Niagara Power Transmission to Buffalo.**—Our Niagara Falls correspondent writes us that the Niagara Falls Power Company has filed with the Board of Public Works of Buffalo the plans for the distribution of Niagara electric power in that city so far as the Company is prepared to place them on record. This action is in accordance with the franchise granted to the Company. In regard to one of the two proposed trunk lines, it is stated that this line will be composed of a pole line consisting of poles not more than 100ft. nor less than 50ft. apart. The conductors for the delivery of the 10,000 H.P. generated at Niagara will consist of not less than three nor more than nine copper cables, each about $\frac{6}{10}$in. in diameter, not less than 22ft. from the surface of the ground, and, at places of special crossing, of greater height. The conductors are to be carried upon porcelain insulators of special pattern. From this trunk line it is proposed to construct two lateral lines. These lines are to be underground, in conduits of cement or vitrified clay of the type known as the Powers tellmic duct or the H. B. Camp Company's duct. Each of the conduits is to be laid so that the top surface will be not less than 18in. below the street, and each will contain not less than 18 holes, each hole not less than 3in. in diameter. The conductors used in each of the conduits are to be cables of copper wire; each cable being completely covered with insulation of standard vulcanised rubber. These underground cables, from the main lines on the canal lands to the points of use, are to carry not more than 20,000 volts. The second trunk line may be erected upon the lands of the New York Central and Hudson River Railroad Company, known as the Belt line, and will consist of a pole line similar to that already described. The first trunk line will be run alongside the canal.

## INCIDENTS OF CABLE LAYING ON THE AMAZON.

Before an appreciative audience at the Royal Institution last Friday, Mr. Alexander Siemens delivered an interesting lecture on "Cable Laying on the Amazon River," in which he recounted his experiences and adventures during the voyage of the cable-ship "Faraday" up the mighty Amazon last January and February. The lecture was interspersed with many anecdotes, which, since they show the humorous and adventurous side of the undertaking, we have reprinted for the delectation of our numerous readers who are interested in cable matters. The lecturer commenced with a description of the preliminary undertakings:—

When it had been decided to connect Belem the capital of the State of Pará, by means of a subfluvial cable, with Manaos, the capital of the State of Amazonas, a preliminary journey became necessary, during which landing places at the various stations had to be selected, some reaches of the river explored, as no reliable charts exist, and various other details ascertained in order to facilitate the laying of the cable. This preliminary survey took place in October of last year, during the hottest season, when the river was at its lowest; while the cable was laid during January and February of this year, when the rainy season had commenced and the river was rising. The difference in temperature between the two journeys was, on the average, not more than 5½°C. (10°F.), but a great advantage during the laying was the almost continuous presence of clouds, which mitigated the fierce heat of the sun and kept the temperature at a very pleasant level.

In regard to the unreliability of the charts just mentioned, the lecturer told us at a later stage that in an adjoining room we should find maps showing the course of the cable up the river, and that in these maps we should see that the cable-ship "Faraday" had contrived to lay the cable right across several islands! It was, however, he said, the maps and not the cable-ship that had gone wrong. Some idea of the magnitude of this river cable scheme may be gathered from the following details as to the size of the Amazon:—

A glance at the map of South America explains without much comment how immense the volume of water must be which is collected from an area measuring more than 2½ million square miles, for the most part covered with dense forests. With several other large rivers the Amazon shares the fate that its name changes several times during its long course, and that at various times different affluents have been considered to be the true source of the main stream. Most geographers, however, regard the Marañon as the principal river, a branch of which, called Tunguragua, rises in Lake Lauricocha in Peru in 10° 30′ S. lat., and 76° 10′ W. long.; although the Ucayale, where it unites with the Marañon at Nauta (4° S. lat., 73° W. long.), is quite as important as the Marañon. If the greatest distance from the mouth is to decide the question, then the source of the Apurimac, an affluent of the Ucayale, can lay claim to being the origin of the Amazon, rising in Peru in 16° S. lat., and 72° W. long.

From the Lake Lauricocha the main direction of the Tunguragua and the Marañon is to the N.N.W. until the river turns eastward, and shortly after passing Jaen breaks through the Andes, entering the plains of the Amazon valley by the Falls of Manseriche, a short distance west of Borja. Its further course is a little north of east until it pours its yellow waters into the Atlantic under the Equator, between the Cabo do Norte and the Cabo Maguari, which are 158 miles apart. This distance is just about equal to the distance from Land's End to Cape Clear in Ireland, or from Brighton to Falmouth. Even west of the island of Caviana, which lies in the mouth of the river, together with the island of Mexiana and several smaller ones, the width of the main stream is over 50 miles, equal to the distance from Portland Bill to the Cap de la Hague. The part of the Amazon flowing north of the island of Marajó may therefore be compared in width to the English Channel, but in depth and volume of water it far surpasses it. It is a disputed question whether the water flowing south of Marajó, commonly called the Pará river, should be considered as part of the Amazon or not. A network of natural canals, "the narrows," connects the two waterways west of Marajó, but the influence of the tide makes it difficult to decide whether part of the water of the Amazon finds its way south of Marajó or not. Along the whole course of the Amazon, commencing at the foot of the Andes, a similar network of islands and canals is formed on both sides of the river, as the whole country is almost level, and is consequently inundated during the rainy season for hundreds of miles by the rivers flowing through it. The most notable exception to this general state of things occurs at Obidos, where the whole volume of water is compressed into one channel a little over a mile wide and said to be about forty fathoms in average depth. A sounding taken opposite Obidos about a third of the distance across the river showed a depth of 58 fathoms measured by a steel wire and Lord Kelvin's sounding machine.

With such uncertain charts, and in the face of such rapid currents as were found to occur in many parts of the river, special sounding apparatus had to be used in order to ascertain where there was deep enough channel for the cable steamer:—

As the current of the river averages three knots in the main channel, it is not easy to take soundings by an ordinary lead line and even with the steel wire an extra heavy weight (33lb.) has to be employed, or the results are not reliable. Besides the wire sounding machine a submarine sentinel was used on the preliminary voyage, wherever serious doubts existed about a channel through which the cable was to be laid. This apparatus consists of a small winch from which a wire leads into the water and drags at a short distance behind a piece of wood, shaped like an angle iron, in a nearly upright position. The wire is not attached directly to the piece of wood but to a string kite fashion, and the wood is fitted with an iron foot which on coming in contact with the bottom of the water releases one end of the kite string, so that the wood remains attached to the winch wire with one end only. The consequence is that the strain on the wire is suddenly reduced to a very small amount, and the piece of wood appears on the surface of the river. It depends on the quantity of wire paid out how deep the kite or the sentinel floats, and its action is quite reliable, so that it is unnecessary to take soundings by the line or by wire while the sentinel is being dragged by the ship. Usually the sentinel was set at five fathoms, and when it struck a bar the ship was stopped and a series of soundings taken to ascertain the exact depth of water and the extent of the shallow place.

A further difficulty in sounding originated from the soft nature of the soil, which for the greater part of the Amazon valley is alluvial clay, and allows the lead to sink into it for several feet. In the narrows there appears, however, a bank of hard clay, called tabatinga, which unfortunately blocks nearly all the branches of the narrows and creates bars all along the course of the Tajipuru, the main westerly waterway connecting to the Gurupa branch of the main river. Occasionally the same hard clay forms shallows in the main river, but as a rule the section of all the channels resembles the letter U, *i.e.*, the sides are very steep and the bottom flat. In this respect, as in many others, the Amazon differs entirely from the Indian rivers, which build up their beds above the surrounding country, occasionally breaking through their natural banks and seeking a new bed. The Amazon, on the other hand, carries with it only the light clay sediment which forms the soil of the whole valley, and the inducement for the main stream to alter its course is therefore very small, and long straight reaches are the result.

Under these circumstances the largest vessels can ascend the river nearly to the foot of the Andes. But the constantly changing sandbanks at the mouth of the Amazon proper make this approach of the river dangerous, and the State of Pará is for obvious reasons not over-anxious to have the deep channels properly buoyed and surveyed. This forces all the shipping to enter the Pará river and to pass the narrows if the Amazon is the goal of the journey. In doing the latter the choice for large ships lies between one of the channels (called furos) with a bar, where it joins the Tajipuru, and a furo, the Macajubim, which has plenty of water, but which winds about in such a serpentine fashion that only ships with twin screws can pass it unassisted. These difficulties are, however, much diminished during the rainy season, when the river rises to such an extent as to drive all the inhabitants of its banks into the towns which have been built wherever a natural eminence secured the inhabitants against the flood.

At Pará the cable steamer could not approach close enough to the shore to land the cable, so the shore ends were laid with the help of a barge and a tug. This method was also adopted at some of the other stations, as, for example, the sections from Pará to Pinheiro, and from thence to Mosqueiro. The section across the Pará river to Souré was laid by the cable steamer "Faraday."

At Souré the ss. "Faraday" was anchored at a convenient distance from the shore, so that the shore end might be landed direct from the ship, and as long as the tide was rising this plan appeared excellent. By the receding tide, however, a whirlpool was formed with the ship lying right across the centre, and *when it had been turned 17 times in one hour* the captain was tired of it, and moved the ship to a safer anchorage.

Another section of the cable, forming a branch from Pará to Cametá is laid in the river Tocantins. The upper reaches of this long river above Cametá are navigable, but are cut off from direct telegraphic communication on account of some rapids not far above Cametá.

Laying the main cable up the Amazon river from Pará to Manoas, and the branches up the numerous important tributaries, afforded occasion for many exciting incidents, out of which, however, the "Faraday" and everyone one on board emerged with safety. We may here remark that the "Faraday" had the distinction of being the first European steamer to navigate some parts of the Amazon; in fact, neither the pilots nor the inhabitants knew of any foreign vessel having previously touched at some of the ports.

The first station on the main cable is Breves, the centre of the rubber trade of the islands of the lower Amazon, situate in the centre of "the narrows." Between Pará and Breves is only one shallow passage, near the lighthouse of Gujabal, and the pilot managed to run the ship aground there. Luckily it was low, tide and with the rising tide the ship could be turned. At Breves the ship was anchored close to the shore and its stern secured to a tree by a rope, so that the tide could not cause it to swing. Under these circumstances the landing of the shore ends was an easy matter and soon finished. The ship then resumed its way into the narrow furos, described above, and the night did not put a stop to its progress, as the outlines of the forest were clearly visible against the sky and the water everywhere more than seven fathoms deep.

Digitized by Google

While the speed of the ship was kept at about six knots, the pilot ordered the quartermaster to put the helm a-starboard, as he wished to increase the distance between ship and shore. The quartermaster was, however, confused, and put the helm hard a-port, with the result that the bows went into the forest until the branches of the trees touched the fore-yard. To appreciate the situation it should be mentioned that the fore-masts stands 74ft. abaft the bows, and that the fore-yard is 69ft. above the water level. Luckily, the soft ground, the elasticity of the forest trees and the steepness of the banks rendered this accident quite harmless, and on reversing the engines the ship at once came off, so that the laying could be resumed.

Mr. Siemens had told us that where the charts seemed to show the cable laid across river islands it was the charts and not the "Faraday" that had erred. But in this instance it would appear as though the steamer had attempted to rival the charts, and was desirous of creating a precedent in the art of cable laying. Nor was this the only instance where the peculiar difficulties of steaming up the Amazon made the "Faraday" evince a strong desire to get out of the water. The neighbourhood of the assault on the forest was the scene of further adventures:—

Not far from this spot the Aturia furo branches off, through which th cable had to be laid, but which was impassable for the ss. "Faraday" on account of a two-fathom bar at the Tajipuru end of the furo. As a splice had to be made with some cable on a barge from which it was to be paid out through the Aturia furo, the "Faraday" had to be anchored, and the right hand shore was approached so as to leave room for the ship to swing round when the tide turned. At the critical moment, when the anchor was to be lowered, somebody blundered and turned the electric light out, leaving the anchor winch and its surroundings in darkness. By the time this mistake had been rectified the ship was dangerously near the shore, and even the anchor could not sufficiently check its advance, so that it ran again ashore, stopping within about 5ft. of a house, much to the alarm of the inhabitants.

This manœuvre fixed the ship in a most convenient position, so that it was left there until the splice had been finished and the tug "Cochrane," with the barge, had started laying the cable in the Aturia furo. Again, there was no difficulty in backing the ship off the bank; but the furo proved to be too narrow to turn the ship, which had to return to Breves, or rather a few miles beyond, to the mouth of the Boiuassu, in order to enter the furo grande and the Tajipuru in a roundabout way. As the ship was drawing over 24ft., and the bar at the end of the Boiuassu had only 23ft. of water at high-tide, the result was easily foreseen; but the ship remained on the bar for nine days, by which time sufficient cable had been transferred to the barge and to the ss. "Malvern" to enable the ship to continue her journey.

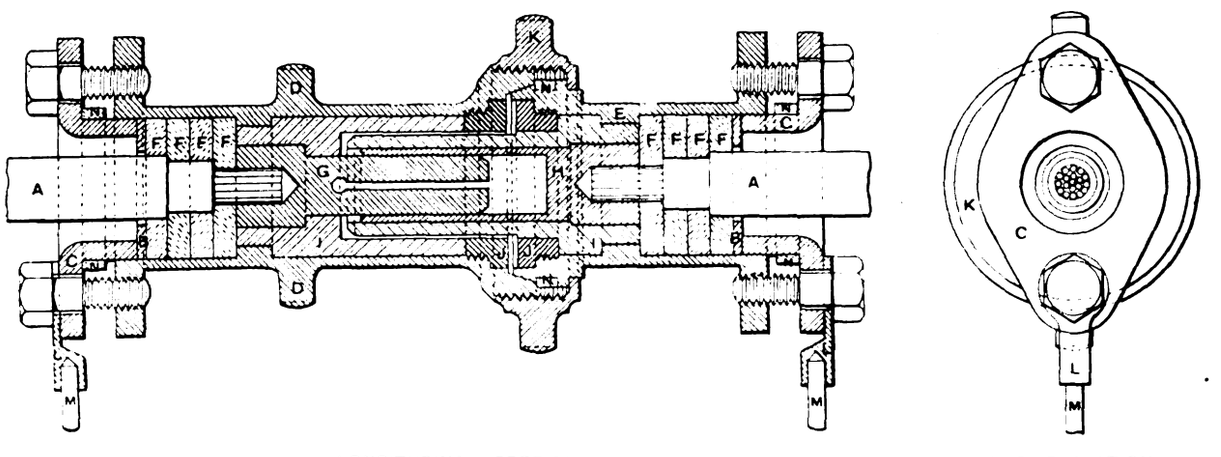
Great demonstrations of joy were frequently made at the landing of the shore ends at the various stations. The streets were decorated with flags, all the inhabitants turned out *en fête*, and the municipal authorities assembled in their best cotton garments to do honour to the important occasion. At one place a native band with native instruments of music went on board a native vessel and circumnavigated the "Faraday" to "express joy." Here is another good story, which will serve to illustrate the jubilations over the advent of the cable which were frequently made:—

In Gurupá, the second station of the main line, the inhabitants expressed their joy at being put in communication with the rest of the world by actively helping in the land of the first shore end. A young lady in white, niece of the Mayor, borrowed a handkerchief from one of our engineers, daintily laid hold of the end of the cable and triumphantly carried it into the station. Here a ball was started and the happy couples waltzed round the cable end to show their appreciation. Meantime the tug began pulling on the barge from which the cable was to be paid out, and just as these vessels began to feel the current, which runs rather strong there, something jambed, the cable would not run out and the tug could not hold the barge against the current. Barge tug and cable drifted down stream, the end gradually disappearing out of the station: This *contretemps* luckily did not disturb the dancers, who continued their rejoicings until the end had been brought back.

During the lecture a number of photographic views of the beautiful scenery to be met with in the Amazon valley were thrown upon the screen, also views of the ss. "Faraday"; and in the adjoining library, as well as on the lecture table, various collections illustrating the indiarubber industry, the flora and fauna of the district, and the habits of the people, were exhibited.

## A HIGH-PRESSURE CABLE COUPLING.

The accompanying illustration shows a longitudinal section and end elevation of a form of coupling for high-pressure electric light and power cables, invented by Mr. Leonard Penson. The outer casings, D and E, are of gunmetal with porcelain or ebonite linings, I, secured by nuts of vulcanised fibre, J J, at the parts where the terminals, G and H, are placed. In order to ensure a water-tight union between the two outer casings, these are ground to a cone, which is held securely in place by the coupling-nut K. A rubber washer, N, is placed between the flanges around the coned coupling to further ensure a water-tight and elastic fit, the washer taking its seating before the cone has been forced home. In making the joint the terminals are first withdrawn and the ends of the cable conductors sweated into place, as shown in the illustration. After this has been done the terminals are replaced, and the series of rubber washers, F F, are closed upon the cables by tightening up the end glands, C, by means of the studs shown.



LONGITUDINAL SECTION END ELEVATION

Penson's High-Pressure Cable Coupling; Half Full Size. A A, Cables. B B, Brass Washers. C C, Glands. D, Outer Casing. E, Outer Casing F, Rubber Washers. G, Terminal Plug. H, Terminal Plug. I I, Ebonite or Porcelain Insulation. J J, Black Fibre Nuts. K, Coupling Nut. L, Terminal for earth connection. M, Earth Connection. N, Rubber Rings.

An earth connection, M, is made at each end of the coupling by a joint to one of the studs on each end gland, the earth connection being made by a short length of flexible conductor.

The couplings are carried in the pavement or road boxes by cast-iron supports or bridge pieces, fixed across the surface boxes. These supports are provided with terminals, to which the ends of the earthing conductors are secured. To ensure safety in making the coupling the outer casings are covered with ebonite caps, thus preventing accidental contact with the live ends. And to prevent a cross connection one coupling is coloured red, while the fellow to it in the same box is black.

Digitized by Google

When this form of coupling has to be adapted to concentric cable it requires to be somewhat modified. In such a case a length of ordinary cable about 3ft. 6in. long is jointed on to the inner conductor, and after the outer conductor has been cut back, a length of cable of the same length is T'd on to it, the whole joint being vulcanised in the usual manner.

Handy, safe, and cheap connecting pieces for both high and low-pressure covered cables are a great desideratum, especially where it may be necessary to make quick and frequent temporary disconnections. The Penson cable coupling, just described, promises to be as useful in these respects as the "Simplex" coupling for low-pressure mains, which Mr. Penson designed some time ago, and which has been used on several public supply systems. We understand that both these forms of couplings are manufactured by Mr. A. C. Hands, of London.

## A PRODUCER-GAS-ENGINE ELECTRICAL PLANT.*

BY ALBION T. SNELL.

The electrical plant at Messrs. R. Maclaren's iron foundry in Glasgow presents several points of interest, on account of the use of large gas engines with producer gas plant. The following information has been supplied by the contractors for the whole of the work, Messrs. Mavor and Coulson, of Glasgow.

*Scheme.*

The object of the plant is to displace some old and inefficient isolated engines supplied with power from a battery of three old Lancashire boilers through long ranges of steam piping. It is intended ultimately to put down three Tangye gas engines, each capable of running continuously at 120 B.H.P., and of giving 150 for a short period. These engines are to be supplied with producer gas derived from two gas generators, each of which is to be large enough to run two of the engines. At present one gas generator and one gas engine are installed.

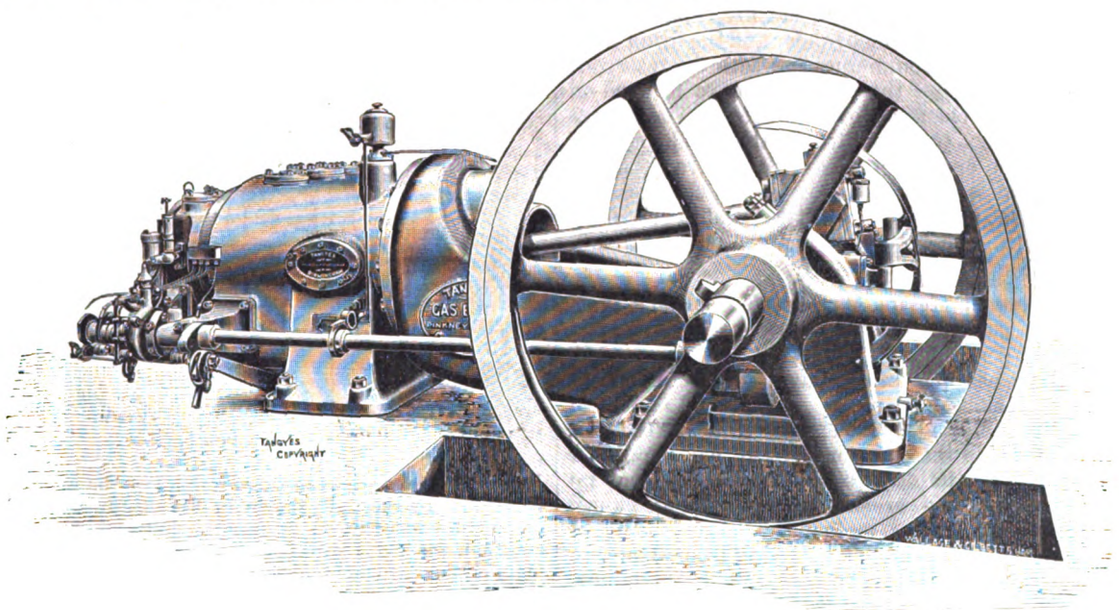
The first engine drives a 67-kilowatt dynamo by belting, a set of hydraulic pumps also by belting and by ropes, a line shaft from which are driven by two belts two heavy loam mills. Although the latter are situated only a short distance from the power-house, experience with electric motors in other parts of the works has led Messrs. MacLaren to regret that they have not adopted motors for the mills. The hydraulic pressure pumps serve an hydraulic accumulator supplying the cranes fixed throughout the foundry. The pumps are fitted with fast and loose pullies with striking gear controlled automatically from the accumulator.

The dynamo drives various motors and also supplies power for lighting the yard and shops by "Jandus" arc lamps and incandescent lamps.

*Power Station.*

This comprises at present the gas producer plant, one gas engine and one dynamo.

The gas producer plant is made under Pinkney's patents by Messrs. Tangyes. It is of very simple form, and consists of a generator, a small vertical steam boiler for blowing air over the fuel, galvanised-iron cooler, hydraulic box, coke scrubber and a gas receiver of 15ft. diameter, having a storage capacity sufficient for two of the engines. The coke scrubber receives the gas after it has passed through the cooler. On the top of the scrubber is a star-shaped pipe with a number of holes in each arm through which are forced jets of water, which wash and cool the gas before it enters the receiver. The generator has a special form of hopper, more lofty than the usual type. This is kept full to the top, and the coal is arranged to fall regularly down to the fusion zone, and is thus heated gradually to the desired temperature. It is claimed by the makers that this gradual heating of the fuel entails less attention to the firing than with producers in which the fuel must be kept at a fixed level, and also that a more uniform quality of gas is realised. The superheater, for heating the steam before it passes into the blower, instead of being placed inside the boiler passes through the inside of the gas delivery pipe. Part of the heat, which would be otherwise wasted, is thus usefully employed.



120-B.H.P. Single Cylinder Gas Engine, by Messrs. Tangyes.

The plant is designed for the addition of a second producer and cooler without material alteration to the existing arrangements.

*Gas Engine.*

The gas engine is one of Tangye's single cylinder engines with Otto cycle. The cylinder is 24in. in diameter by 30in. stroke, and the piston speed is 750ft. per minute, corresponding to 150 revolutions of the crank-shaft. There are two flywheels, each 9ft. in diameter by 15in., face turned for belt driving. They weigh three tons each. These are comparatively light for the size of engine, but are found to be sufficient owing to the peculiar form of the combustion chamber, which tends to reduce the shock upon the crank pin, and to make the pressure uniform throughout the power stroke.

This chamber is horned shaped, and the charge is fired from the small end, and gradually expanding into the large end gives a gradual rise of pressure, and thus avoids a heavy initial shock. The steady running of the lamps which are

* All rights reserved. From a forthcoming work.

Digitized by Google

coupled to the dynamo driven off the engine is a proof of the even running of the engine. In addition to the flywheels, there is a multiple grooved wheel for a rope drive, mounted upon a main shaft and coupled to the engine shaft through an Edmiston friction clutch. The crank shaft is 9in. in diameter, and is extended to bearings in wall boxes on either side of the engine. When working with a charge compressed to 80lb. per square inch, the initial pressure is about 240lb. per square inch, and the mean pressure about 70lb.

The usual water circulating system is employed, cold water entering the cylinder jacket below and leaving at the top. The tank is placed above the engine, and forms the roof of the engine house. This method of cooling the cylinder causes an unequal expansion of the top and bottom of the cylinder which though not of serious importance in small engines is likely to cause trouble in large ones. To obviate this Messrs. Tangye arrange the cylinder in a special way which it is claimed maintains it truly circular under all conditions of working. The exhaust is made through two valves, a large and a small one. The small one is opened first, and relieves the maximum pressure, and then the large one is opened by the same cam. The exhaust box is water jacketed. The exhaust is delivered into two silencers in parallel, and from them is led by two pipes into the atmosphere at the top of the engine house. The silence of the exhaust is claimed as one of the features of the engine. The starting arrangement consists of a "baby" gas engine coupled direct to a small pressure pump, which forces a charge of air and gas into a reserv ir, from which it is discharged into the combustion chamber of the engine at any desired pressure. When starting the engine crank is placed in the usual position, at which the ignition valve is kept tight upon its seating, and thereby cutting off connection between the cylinder and the firing tube. The cylinder is then put in communication with the reservoir, the pressure in which causes the piston to move forward on the power stroke and to open the ignition valve. The charge then presses into the hot tube and fires in the usual way. It is possible to start the engine in this way with from half to three-quarter load on it without taking off the compression. The governor is of the centrifugal ball type, and is driven by scroll gear fixed to the side of the cam shaft.

*Dynamo.*

The dynamo is one of Messrs. Mavor and Coulson's type, made under Sayers' patents. It has an output of 67 kilowatts at 600 revolutions per minute, giving 610 amperes at 110 volts. It has three bearings and a heavy cast-steel flywheel, mounted on an extension of the shaft. The special feature of this machine is that the lead is fixed; and although the load varies largely, it is found that the commutator has acquired a fine dark purple skin on its surface, thus indicating that no sparking takes place. The brushes are of copper gauze. This dynamo runs a number of motors, the largest being of 25 B.H.P. capacity, and the remainder varying from 3 H.P. to 10 H.P. It also supplies current to large Sunbeam lamps, small incandescent lamps, and "Jandus" arc lamps, connected singly across the 110-volt mains.

*Motors.*

The largest of the motors has a capacity of 25 B.H.P., and drives the mechanics' shop. It is of the open type, and is belted to the shafting by a belt.

The other motors vary in capacity from 10 B.H.P. to 3 B.H.P., and are distributed about the works. They are all of the enclosed type, on account of the dust and dirt incidental to foundry work. They run elevators, machine tools, &c. In most cases they are coupled to the machines by belting.

The efficiency of the 3 H.P. motors is stated by the makers at 87 per cent., and that of the 10 H.P. motors at 90 per cent. The particulars of one of the latter sized motors with figures of test were given in *The Electrician* for January 10th last, on pages 341—343.

*Method of Distribution.*

The whole of the wiring is carried out on Messrs. Mavor and Coulson's concentric system with lead-covered outers, the outer being earthed. The switch boxes, resistance boxes and terminal boxes are all made of cast iron, with dust and damp-proof covers. The system admirably meets the exceptional conditions to be encountered in an iron foundry.

The mains from the dynamo are lead to a main switch and distribution board, upon which are mounted switches, fuses and ammeters for the various lighting and motor circuits. Each of the large motors has a separate single-pole switch and fuse and an ammeter.

*Working.*

It is found that the gas engine developes power at the rate of 1 B.H.P. per pound of anthracite coal, and allowing for losses in the dynamo, cables and motors, power is generated and distributed to the motor shafts for 1·25lb. of anthracite per horse-power hour.

The experience gained with the present plant is so satisfactory that Messrs. MacLaren contemplate at an early date the erection of a duplicate one to displace a further batch of isolated engines in the same foundry.

## EXPERIMENTAL TESTS ON THE INFLUENCE OF THE SHAPE OF THE APPLIED POTENTIAL DIFFERENCE WAVE ON THE IRON LOSSES OF TRANSFORMERS.*

BY STANLEY BEETON, C. PERCY TAYLOR AND J. MARK BARR.

*(Concluded from page 79.)*

EFFECTS OF THE INJECTOR.

As this Paper is essentially one dealing with transformer tests, we do not propose to discuss at any length the effects obtained by the use of the injector, but it may be useful to consider one typical case of injected resistance, and one of capacity. The effect of injecting rather a long resistance, when the current is *not in phase* with the

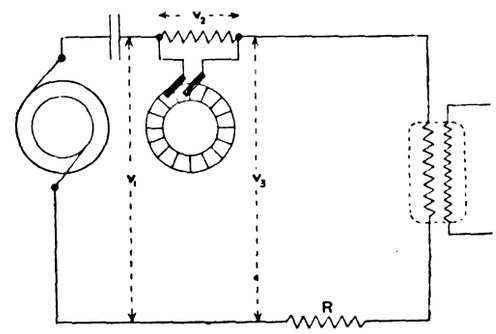


FIG. 5.

P.D. maintained between the terminals of the transformer is well illustrated by the wave shown in Fig. 3. In this test a resistance of 36 ohms was thrown in over the first part of the wave; but, in addition, we had a capacity of 96 microfarads *permanently* in the main circuit, which brought the current into phase with the P.D. between the terminals of the alternator. By bringing the current into phase with the P.D. we mean that the zero readings of the two waves occurred at the same point, but the waves, of course, possessed very different shapes.

The distinguishing feature of this wave is the curious sort of hump which occurs just at the beginning. The explanation of this is not hard to find. It will be observed that during the interval in which the current is opposite in sign to the P.D. the ordinates of the latter curve tend to increase, but directly the current-wave crosses the zero line the P.D. begins to decrease. Consider for a moment the instantaneous P.D.'s between the terminals (1) of the machine and condenser, (2) of the injector, (3) of the transformer and resistance R, represented by $v_1$, $v_2$, $v_3$ (Fig. 5) respectively, during the interval just alluded to. Since the current is in the opposite direction to the terminal P.D. of the transformer, we have:

$$v_1 = v_3 - v_2;$$
$$v_3 = v_1 + v_2;$$

that is to say, for this short interval the P.D. across the transformer equals the sum of the P.D.'s of the machine and the injector. This, then, fully accounts for the presence of the *hump*.

The effects obtained by the injection of capacity will be best explained by a reference to Fig. 6 and Fig. 7. In the latter we have shown (curve A) a P.D. wave at the terminals of the trans-

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

former and non-inductive resistance R (Fig. 6). This was obtained by adding, at each point, the drop in pressure due to this resistance to a curve obtained at the terminals of the transformer, and shown in Fig. 4 G. The interval during which the condenser (60 microfarads) was in circuit is also shown in Fig. 7, and the curve of P.D. between its terminals (*i.e.*, the brushes $b_1$, $b_2$, Fig. 1.), marked B, was obtained by integrating the current-wave during this interval.

By combining these two waves we get the P.D. between the terminals of the alternator, shown in curve C. Since the condenser P.D. is obtained by integration, its maximum necessarily occurs when the current crosses the zero line. This maximum value is directly proportional to the area of the current curve from the point of injection to its zero point, and inversely proportional to the capacity of the condensers injected.

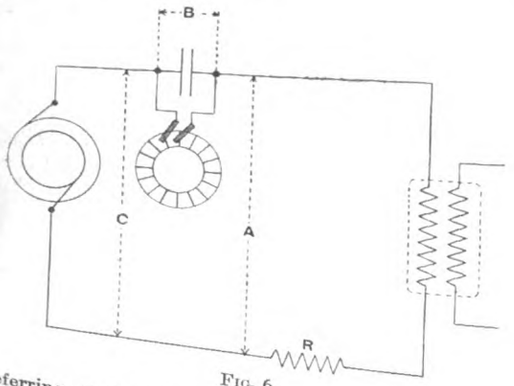

FIG. 6.

On referring to Fig. 7, we note that, since the current is large when the condenser is thrown into circuit, the curve B rises very rapidly, and therefore the curve A turns down very rapidly away from curve C, and crosses the zero line where B and C cross each other. The maximum point of the condenser P.D. curve, of course, occurs at the same time as the maximum *difference* between curves A and C, and thus, when the curve B turns down, A bends over and begins to approach C, which it crosses when B crosses the zero line. Soon after this the condenser is short-circuited, and thus B follows the zero line and A is again coincident with the alternator P.D. curve C. This coincidence lasts as long as the condenser is cut out of circuit by the "injector." The points marked

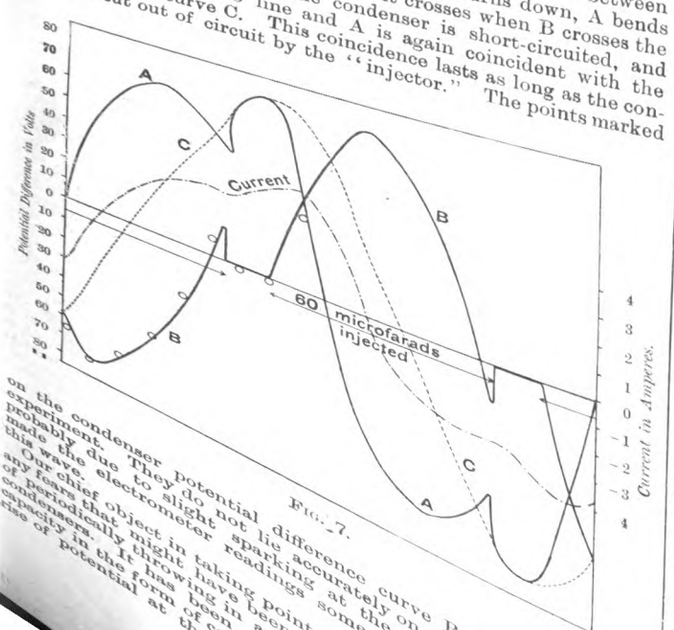

FIG. 7.

on the condenser potential difference curve B were obtained by experiment. They do not lie accurately on the curve, but this is probably due to slight sparking at the injector brushes, which made the electrometer readings somewhat unsteady when taking this wave.

Our chief object in taking points on this curve was to set at rest any fears that might have been entertained as to the advisability of periodically throwing in and removing from a circuit a bank of condensers. It has been shown that when a circuit possessing capacity in the form of condensers is broken there may be a sudden rise of potential at the terminals of the latter. No such rise of P.D. was observed in our experiments, and this was due to the fact that the condenser circuit was *never really broken*, for the capacity was removed from the circuit by being short-circuited.

### DISCUSSION OF RESULTS.

Our great aim at the time of carrying out these experiments was to find some definite law connecting the iron loss in the transformer with the shape of the applied P.D. wave. In no work published on the subject at that time could we find any results or conclusions which could form the basis of a connected theory regarding this question. None of the investigations on this subject had justified any conclusion which could materially help in judging of the exact, or even relative, value of wave forms not actually tried. The conclusions that we came to were—

1. That if the R.M.S. value of the applied P.D. is constant, and the area of the P.D. wave is constant, then, whatever be the shape of this wave, the total iron loss cannot vary.

2. That if the R.M.S. value of the applied P.D. is constant, but the area of the P.D. wave varies, then, whatever be the shape of this wave, the total iron loss will vary by an amount which is only dependent upon the area of the P.D. wave.

We feel fully justified in coming to these conclusions, for, as we have shown above, the hysteresis loss depends only on the area of the P.D. wave, and we have proved experimentally that the eddy-

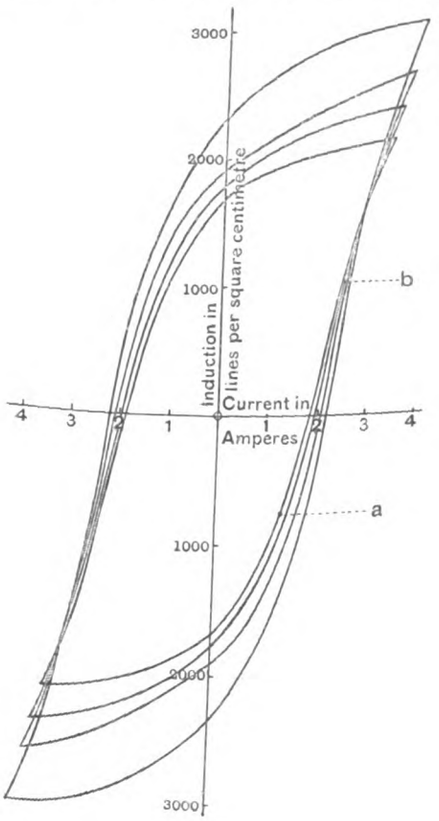

FIG. 8.

current loss is constant for a given effective P.D. This we refer to again below. The results calculated from our tests will be found in as concise a form as possible in Table I.

*Hysteresis Tests.*—In order to get a complete theory regarding the iron losses, it was essential that we should separate those due to hysteresis and to eddy-currents. To determine the former loss, then, hysteresis tests were made on the transformer itself by a method independently suggested and used by Prof. Ewing* and Dr. Hopkinson. We found this method most satisfactory. The two 12-turn coils of the transformer were used, one as the magnetising and the other as the test coil. A large resistance was put in series with the magnetising coil to reduce the time constant of the circuit.

The magnetising current was measured by means of a standard Weston ammeter, while in series with the test coil we had an Ayrton and Mather narrow-coil ballistic galvanometer, which was standardised with one of Hibbert's magnetic standards. In this way four complete B-H cycles, as shown in Fig. 8, were determined for the transformer. They were integrated with an Amsler polar planimeter, and the results obtained were plotted to show the relation between the maximum induction and power lost in hysteresis, at a frequency of 100 ∿. This curve is shown in Fig. 9. The hysteresis loss for each test was obtained by calculat-

ing the maximum induction as previously shown, and referring to this curve, and the eddy-current loss by subtracting this from the total.

*Variation of Applied P.D.*—It will be observed, on reference to Table I., that the effective values of the applied potential difference are not all the same: they vary between 48 and 50 volts.

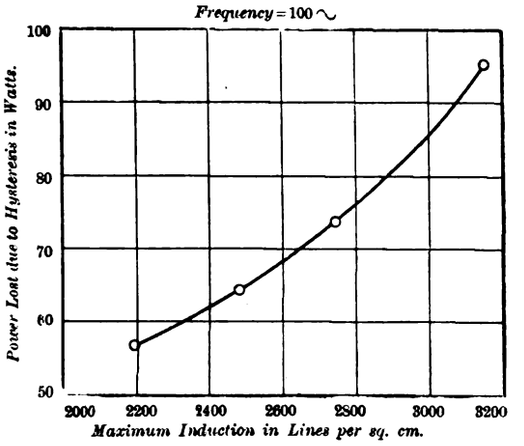

FIG. 9.—Curve showing the Relation between the Maximum Induction and Power Lost in Hysteresis in a 3-kilowatt Mordey Transformer.

This is due to the fact that they are not instrument readings, but are calculated from the curves by means of the first moment planimeter. The method of using this instrument to give the R.M.S. value of a curve was described in the articles referred to elsewhere.* It was due originally to Mr. Turner, one of the demonstrators in the mathematical department of the Central Technical College. We have given preference to this method of obtaining the effective value of both P.D. and current mainly for two reasons, viz.: Firstly, far greater accuracy is attainable by this method. This is easily understood when it is remembered that, by increasing the number of water cells used in conjunction with the electrometer, this instrument could be made as sensitive as we wanted, whereas the sensibility of the voltmeter was fixed. Secondly, by calculating *all* results from the curves of P.D. and current, any small errors which arise from inaccurate readings or drawing appear in them all, and these are made of far less relative importance. The voltmeter V (Fig. 1) was therefore only used to keep the effective value of the P.D. constant throughout each test, and it was not specially calibrated. This method of calculating the results has, however, introduced some difficulty in drawing conclusions from our experiments, as the small variations in effective P.D. must be taken into consideration. The difficulty of arriving at the true effect of this variation arises mainly from

* *The Electrician*, July 1895, Vol. XXXV., p. 290.

the fact that the eddy-current loss has been obtained by taking the difference of two much larger quantities, and thus the probable error is a large percentage of the whole range of variation. After a careful study of columns 2 and 7 of Table I., we came to the conclusion that within the limits of accuracy attainable by our experiments—*i.e.*, about ½ per cent.—the eddy-current loss is proportional to the square of the applied P.D. This leads at once to the further conclusion that *the eddy-current loss is independent of the wave form of P.D. so long as its R.M.S. value is constant.*

In order that this variation of applied P.D. should not obscure the true meaning of our results, we have calculated by known laws the difference in the iron losses produced by the difference in the value of the applied P.D. from 50 volts, and thus found the iron losses for each wave-shape corresponding to an applied P.D. of 50 volts. The methods of correction employed were as follows:—The effect of variations in the R.M.S. value of the P.D. is most marked in the case of the eddy-current loss, so that we will deal with this first. We have, then, here corrected the eddy-current loss to a value corresponding to a common effective applied P.D. of 50 volts. In doing this, since each test is corrected separately, we only assume that, *so long as the wave shape of P.D. is constant*, the eddy-current loss varies as the square of the effective volts.

From Table II. we see that, with the exception of the tests shown in Fig. 3 C and Fig. 4 G the eddy-current loss is practically constant, the variation of half a watt meaning only ½ per cent. in the determination of the total loss. Again, for the correction of the hysteresis loss we need only consider laws which hold so long as the wave form is constant. Under these circumstances the area of the P.D. wave varies directly as the R.M.S. value. Now the

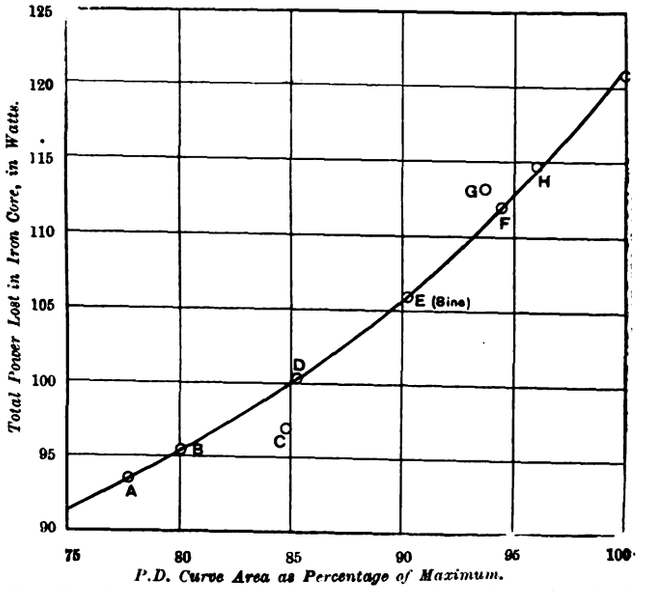

FIG. 10.—Curve showing Relation between the Total Power Lost in the Iron Core of a Transformer, and the Area of the Applied Potential Difference Wave expressed as Percentage of the Maximum Area possible with a R.M.S. value of 50 volts.

The letters A to H refer to the Curves given in Figs. 3 and 4.

area gives us at once the maximum induction, and the corrected hysteresis loss is then got by a further reference to Fig. 9. The values thus obtained are given in column 4 of Table II. The corrected total loss is now determined by the addition of the eddy-current and hysteresis losses, from which we obtain the curve given in Fig. 10.

*The Relation of the Iron Losses to the Area of the P.D. Wave.*

In Fig. 10 we have shown the relation between the total power lost in the transformer and the area of the P.D. wave expressed as a percentage of the maximum area possible with the given R.M.S. value of 50 volts.* This maximum area occurs with the rectangular shape shown in Fig 11.

Such a rectangular wave would give the greatest possible value of maximum induction—in this case 3,020 lines per sq. cm. On reference to Fig. 9, it will be found that the loss due to hysteresis corresponding to this value of maximum induction would be 88 watts; adding to this the constant loss due to eddy-currents—namely, 33 watts—the total power wasted in the iron comes out at 121 watts. This value must, of course, constitute the top limit of the curve shown in Fig. 10, since this wave-shape has the largest area possible with the given effective value. It will be noticed that

* It may be of interest to point out here that the ratio of the area of the P.D. wave to its maximum possible value is the reciprocal of the ratio more recently called by Dr. Fleming the "form factor."

Digitized by Google

we have gone fairly close to the limit in this direction in our experiments. The process of fixing the limit in the other direction consists of finding the shape of P.D. wave which will have the *smallest* area for the given effective value.

Now it will be obvious that before the area of a wave of constant R.M.S. value can be very much diminished *the maximum ordinate must of necessity be increased.* We cannot, therefore, diminish to any great extent the hysteresis loss without necessitating higher insulation. If, on account of this difficulty, the maximum ordinate of the P.D. wave must have a definite limit (*e.g.*, maximum value not to exceed twice the effective value), the shape giving the least iron loss will be that shown in Fig. 12.

This is again rectangular, which may seem curious, but the essential point is to get as wide a peak as possible, and thus, as it were, confine the wave to one part of the period. This wave

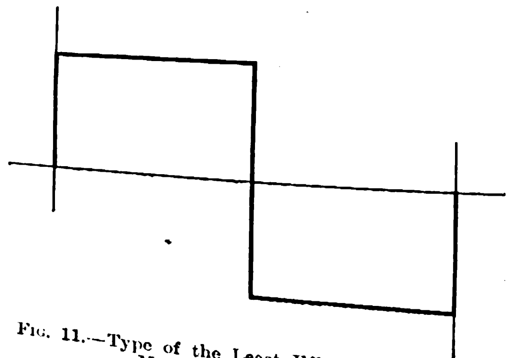

Fig. 11.—Type of the Least Efficient Wave of P.D. Maximum Value = Effective Value.

has been drawn to the same scale as the one given in Fig. 11. The area of the curve shown in Fig. 12 will be found to be exactly 50 per cent. of the possible maximum (Fig. 11); in fact, with waves of this type having a constant R.M.S. value, the area (and, therefore, the maximum induction) is inversely proportional to the maximum ordinate. This gives us a measure of the minimum possible hysteresis loss with different allowable P.D. maxima. It is evident that, *unless* the maximum ordinate of the wave is limited, its area can be infinitely reduced while its R.M.S. value remains constant.

*Advantages of Peaked Waves of P.D.*—Our lowest iron loss is that given by the P.D. curve shown in Fig. 3 A. This is due to the fact that it approaches most closely to the form shown in Fig. 12, thus giving the least area, and, consequently, the smallest

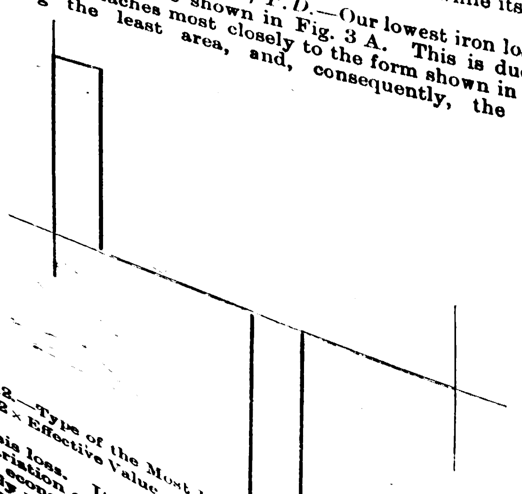

Fig. 12.—Type of the Most Efficient Wave of P.D. when the Maximum Value = 2 × Effective Value. (Same Scale and Effective Value as in Fig. 11.)

hysteresis loss. It will be observed from Table II. that there is a total variation of 22½ per cent. in the total iron losses. The consequent economy of using peaked waves of P.D. of course becomes especially noticeable at low loads, but even at *full* load the saving thus effected is by no means insignificant. For let us assume that the efficiency of a transformer worked off the P.D. wave shown in Fig. 4. H is 95 per cent. at full load, then, if the iron loss is (say) 2½ per cent. of the maximum output, we would increase the efficiency of the transformer to over 95½ per cent. by using the P.D. wave shown in Fig. 3 A.

Under circumstances of cheap power production this saving may not be of extreme importance, but in systems of distribution or transmission of power where large transformers are used, the efficiency of transformation is not the only question to be considered. One of the chief difficulties in designing large transformers is the providing of adequate means for keeping them cool, and any means by which the necessity for special cooling arrangements can be materially reduced will be sure to commend itself to those who have to deal with large transformers.

### No-Load Current.

We have not been able to arrive at any satisfactory explanation of the variation of the no-load current with the shape of the applied P.D. wave. The curve given in Fig. 13, however, is interesting as showing that the maximum current occurs with the sine wave of P.D. The power-factor for this wave, Fig. 4, E is also the smallest (Table I.). This is a distinct point against the use of sine waves of P.D. with transformers, especially in cases where many transformers have to be kept magnetised on light secondary load at the end of long mains; in cases such as these the mains losses—which vary as the square of the current—form a very appreciable item of the whole loss. The difference between the R.M.S. currents in cases A and E, for instance, is 25 per cent., so that the mains losses in case E would be more than 50 per cent. greater than in A.

In order to arrive at a satisfactory explanation of the shapes of the current waves, they must be considered as built up of two components—a hysteresis component and an eddy-current component. We have split them up in this way in Fig. 3 and Fig. 4, the hysteresis component was obtained from the induction curve by means of the B.H. curves in Fig. 8, and the eddy-current by taking the difference between this and the total current curve.

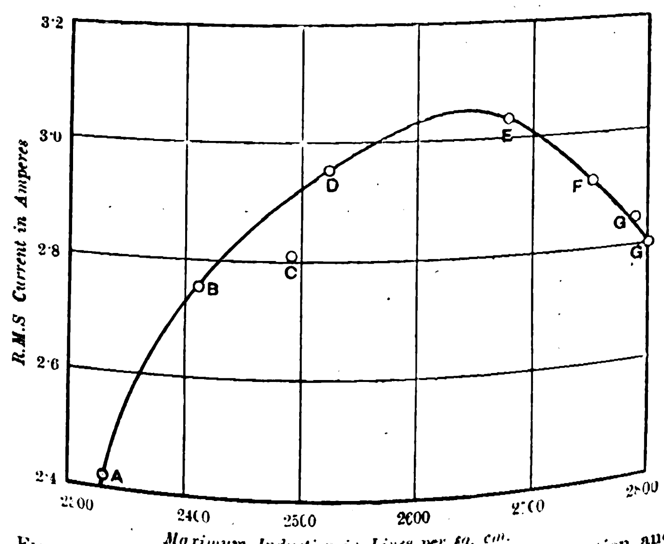

Fig. 13.—Curve showing Relation between Maximum Induction and R.M.S. Current in a 3-kilowatt Mordey Transformer. (From Table I.).

It will be at once apparent that the peculiarities of the current-curves are due almost entirely to the eddy-current component; the hysteresis parts are all very similar in shape. The roundness of the curves, especially noticeable in curves B, C and D, is entirely due to the eddy-currents, the hysteresis component being in all cases comparatively flat on both sides. The eddy-current components have been obtained by a somewhat complex method, and a discussion on the details of each one is therefore hardly justifiable; but as a class they exhibit some very interesting features, the most notable of which is that the curves are very nearly in phase with the P.D. waves. Speaking generally, the curves also have shapes similar to the P.D. waves. This is a clear indication of the fact that the eddy-currents may be considered as equivalent to one current flowing in a supposed secondary circuit. It follows from this that the eddy currents have the effect of bringing the total primary current-curve more nearly into phase with the P.D. wave, and thus tend to increase the power factor. It will be noticed that in all the curves, with the exception of IV. E., Plate 3, the eddy current component leads slightly in front of the P.D. wave; it is, however, so slight that it needs some corroboration from other experiments. The only explanation possible seems to be that the plates of the core, being separated by insulating paper, form a condenser, thus causing a small capacity-current as well as the ordinary eddy-currents.

### Notes on Investigation by Dr. Roessler.*

The conclusions at which we arrived in August were partly anticipated, we found, by Dr. Roessler in a Paper read in Germany

* See *The Electrician*, November and December, 1895, Vol. XXXVI. pp. 124-222.

Digitized by Google

in July, 1895, but not published in England until November. Dr. Roessler, however, since he could only experiment with two wave-forms of applied P.D., could not prove by experiments the results which he obtained theoretically. We gather from an article in *The Electrician* on January, 10, 1896, that Dr. Fleming did not at that time consider it *proved* that the hysteresis loss in a transformer depended only on the form-factor of the applied P.D. wave—or on its area, which comes to the same thing. Dr. Roessler's system of measurement differs very materially from ours. To obtain the power given to the transformer Dr. Roessler employed the usual form of dynamometer-wattmeter, with its necessary corrections, and this gave rise to some rather complex calculations with the different currents. Dr. Roessler treats the question very largely from a mathemetical standpoint, and introduces a correcting factor into his formulæ for each typical wave-shape; but he does not appear to have fully appreciated the fact that the whole question of hysteresis loss is wrapped up in the *area of the applied P.D. wave*, independently of the R.M.S. value. In this paper we have shown that it is this *area* alone which determines the hysteresis loss of a transformer.

Dr. Roessler makes some interesting comments on the equation,

$$E\,p_1 = J_1\,\omega_1 + 0{\cdot}4\,\pi\,\frac{n_1^2}{l}\,S\,\frac{d\,B}{d\,H}\,\frac{d\,J_1}{d\,t},^{*}$$

in which $E\,p_1$ = primary P.D., J = primary current (both *instantaneous* values), $n$ = primary turns, and $l$ and S are respectively the length and cross-section of the path of the lines in the iron. The following sentence occurs:—"If . . . the alternator gives a very pointed potential curve, and very high maximum value, the maximum value of $\frac{d\,B}{d\,H}\,\frac{d\,J_1}{d\,t}$ must be very great. *But* $\frac{d\,B}{d\,H}$ *is independent of the alternate-current curve*" [the italics are ours], "and only depends on the hysteresis curve; hence the value of $\frac{d\,J_1}{d\,t}$, which is simultaneous with the maximum value of the potential curve, must be greater with pointed curves than with flat." This is not necessarily so, and the reason is this—that the value of $\frac{d\,B}{d\,H}$ *is* dependent on the form of the P.D. curve in so much as it is dependent on the point on the hysteresis cycle at which we are working, and this again on the part of the period at which the maximum value of P.D. occurs. Compare Figs. 3A and 3B. In A, when the P.D. is at its maximum, the induction curve has not crossed the zero line, and we are working at the point marked "*a*," Fig 8; but when the P.D. is a maximum in B we are working at the point "*b*," Fig. 8: the value of $\frac{d\,B}{d\,H}$ at *b* is 70 per cent. greater than at *a*, and this is why the current-curve is so steep at the time of maximum P.D. in A and comparatively flat in B, although the maximum P.D.'s in these two only differ by 10 per cent. The steepness of the curve in A is also partly due to the eddy-currents.

In conclusion we wish to thank both Prof. Ayrton and Mr. Mather for their kindness and help throughout these experiments; and we are especially grateful to Prof. Ayrton for the assistance he has rendered us in the preparation of this Paper.

### Appendix.

Before deciding on the method described in this Paper for obtaining potential difference waves of any desired shapes, we considered the practicability of using a series of alternators coupled on one shaft. By this means various component harmonics differing in phase, amplitude, and frequency could be produced and combined to give any desired wave-shape. This idea of combining harmonics to obtain prescribed results has been known for some time. Lord Kelvin used it in his famous tide-predictor, and it was afterwards employed by Profs. Ayrton and Perry in 1877 in their apparatus described in a Paper on "The Music of Colour and Visible Motion."† Although this method would have been in some ways very convenient, we were obliged to dismiss it as too expensive. It is also difficult to get waves of very great irregularity by this method. Dr. Fleming, in reference to this method,‡ remarked that three such alternators, giving frequencies in the ratio 1, 3, 5, would be sufficient for the majority of curves met with in practice. We were anxious, however, to experiment with waves *not* actually met with in practice, since our aim was not so much to find out which alternator now on the market was the best, but rather to give some information, if possible, which might be a guide in the future design of alternators for use on transformers.

On considering the question more fully, we also find that the first three odd harmonics given by the series of alternators just mentioned would not, in many cases of not very distorted waves, give a close approximation to the true shape; thus we find that, in order to get a peak in one part of a wave, it is necessary to cause the rest of the period to consist of a series of irregular undulations. We cannot, in fact, by this method alter one part of the wave without getting into difficulties with the rest of it. This point is brought out very clearly in Fig. 14. Here we show a wave which we have produced by our method of "injection,"* and also

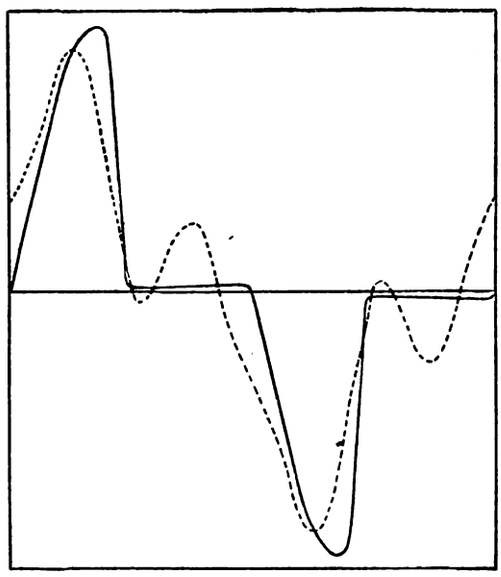

Fig. 14.—The Continuous Line Curve shows Wave actually produced with Injector. The Dotted Line Curve shows Wave that would be roduced by Combing the first three Odd Harmonics.

the wave given by the combination of its first three odd harmonics (dotted curve). It will be noticed that, though this wave approaches the desired shape at the peaked part, it is far from it during the rest of the period. The harmonics for this wave were obtained with one of Coradi's harmonic analysers, by the courtesy

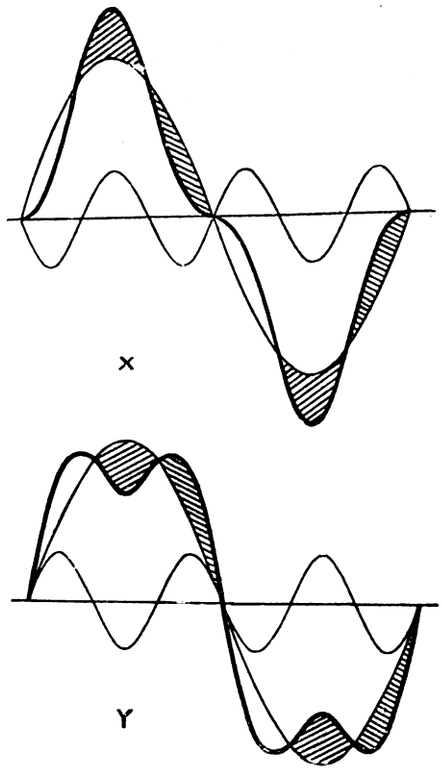

Fig. 15.—X = Third Harmonic in Anti-phase. Y = Third Harmonic in Co-phase.

of Prof. Henrici. It is here that our method has one of its chief advantages. If we want a peak or a depression in one part of our wave, we make it, and leave the rest in peace.

The injector method is also one which may be adopted at very little cost. It may be argued that the condensers are expensive, but they are not *necessary*, as a great variety of waves can be got by injecting resistance, and using more than one pair of brushes ($b_1$ $b_2$, Fig. 1.), and so getting more than one injection on each half-wave. It should also be remembered that, when using condensers, the greatest effect is got with the least capacity. The effect of higher harmonics on the area of a P.D. wave (and consequently on the maximum induction) cannot be stated generally. But it may be of interest to indicate the general principles on which it rests. To do this a simple case may be taken as an example. It is only necessary to consider odd harmonics, as even ones make the waves unsymmetrical about the time line.

Consider the case of a third harmonic superimposed on a fundamental sine wave as shown in Fig. 15. The amplitude of the harmonic is here three-tenths of that of the fundamental.* The two extreme cases are shown, namely, those with the harmonic in co- and anti-phase. The effective value of the resultant is the same in each case (viz , very nearly 4 per cent. greater than that of the fundamental), but in $x$ the area of the semi-wave is *diminished* by that of a half-period of the harmonic, and in $z$ it is is *increased* by the same amount; this is the maximum effect possible, since, whatever the relative phases be, two of the half-periods of the harmonic cancel as regards area. The area of the wave may therefore be *diminished or increased* by 10 per cent. by the addition of the harmonic.

The area of a sine wave of the same effective value as the resultants will be 4 per cent. greater than that of the original fundamental. Thus, by building up a wave of two harmonics such as here chosen, we may get resultants of constant effective value having areas from 6 per cent. greater to 13·5 per cent. less than that of the sine wave of that effective value. It will be apparent from this reasoning that the effect of harmonics is entirely dependent on their phase relatively to the fundamental, and that attempts such as were made at the time of the "Sine Wave Controversy" to state generally the effect of harmonics in the P.D. wave on the iron loss of a transformer are quite futile.

## MAGNETIC DATA AND TESTING OF IRON AND STEEL.

At the ordinary meeting of the Institution of Civil Engineers on Tuesday, May 19th, Sir Benjamin Baker in the chair, two communications dealing with the magnetic properties of iron and steel were considered.

The first Paper was entitled "The Magnetic Testing of Iron and Steel," by Prof. J. A. Ewing, F.R.S. The author referred to the practical importance which now attached to the magnetic testing of iron and steel in relation to the manufacture of dynamos and transformers. From being a mere laboratory experiment, interesting only to students of physics, it had passed into the rank of an engineering operation. Iron makers now supplied material greatly superior, from the magnetic point of view, to that which could be obtained even two or three years ago. In dynamo construction the introduction of permeable steel castings for the field-magnets had given greater latitude as to form without loss of efficiency, the best steel castings being indeed somewhat better magnetically than most forged iron. In stampings of sheet metal for transformers the main consideration was absence of hysteresis, and so great had been the advance in this respect that iron was now readily obtainable with only half the amount of hysteresis which was considered possible a few years ago. This had brought about a notable increase in the efficiency of alternate-current distribution by reducing the large element of loss which occurred through the hysteresis of transformer cores during the hours of light load as well as of heavy load. The author recalled the conventions according to which the magnetic quality of iron was expressed. The most usual test was one to determine the relation of the magnetic induction to the magnetising force, the ratio of B to H being the permeability. To enable H to be determined with accuracy the specimen was arranged as a closed ring, or as an ellipsoid, or as a bar or bars rendered practically endless by the use of a yoke. Ballistic methods of testing were described, and it was shown how in the use of a yoke the proper correction might be experimentally found, to deduce the true magnetising force by allowing for the magnetic resistance of the yoke itself. For this purpose the author used a pair of bars joined by two short yokes at their ends, the yokes being shifted so as to include either the whole length or half the length of the bars in the magnetic circuit. Reference was made to various forms of apparatus designed to measure the magnetic induction by observing the force required to separate surfaces in the magnetised piece, and a form used by the author was described in which a yoke piece was simultaneously drawn away from polar extensions at both ends of the bar. A novel apparatus was shown in detail for measuring permeability by comparing the magnetising force required to produce a given induction with the force required to produce equal induction in a standard bar. This apparatus,* which the author terms a magnetic bridge from its analogy to the Wheatstone bridge for the measurement of resistance, reduced the operation of testing to a comparison between the specimen and a bar the magnetic quality of which had been determined once for all by the instrument maker. The two bars were connected by end yokes, and by varying the number of turns in the magnetising coil on one of them the yokes were brought to the same magnetic potential. The relative number of turns on the two thus gave the relative magnetising forces required to produce the same induction in both. A simple form of magnetic detector showed when the two yokes were brought to the same potential. The manipulation consisted in varying the number of turns acting on one bar by means of dial switches, while the magnetising current was from time to time reversed. This permeability tester was intended for workshop use, and might take its place alongside of the author's hysteresis tester, which was also described. The methods of directly measuring hysteresis were briefly referred to.

A number of representative examples were given of permeability tests of forged wrought-iron, forged steel and cast steel for dynamo magnets; also of hysteresis tests of transformer plate rolled from Swedish wrought iron and from ingot metal. The results were shown by means of numerical tables and also in curves.

The second Paper, on "Magnetic Data of Iron and Steel," was by Mr. H. F. Parshall, Assoc. M.Inst.C.E. Magnetic tests of iron and steel might be conducted to determine such properties as permeability, maximum magnetisation, residual magnetism, and permanent magnetism, and the relation they bore to tempering, annealing, internal stresses, composition, and processes of manufacture. The loss of energy through hysteresis might be determined either magnetically, by determining the area of the loop formed by plotting the flux densities as ordinates, and magnetic force as abcissas, or mechanically by suitable power-measuring apparatus. A study of the magnetic results and of the chemical analysis showed a more or less intimate relationship according to the degree with which the modifying physical conditions might be controlled. In general, a greater degree of purity was an indication of high permeability, but as the different qualities of iron and steel merged into each other by insensible degrees, owing to variations in the processes of manufacture, chemical analysis might be taken only as an approximate indication of the magnetic properties. Carbon was the most important element entering into the composition of commercial iron, and, within the limits that chemical analysis might serve as an indication of the physical structure, the permeability was inversely as the amount of carbon present. The limitation as to the state of physical structure was greatly affected by the state of the carbon, that was, whether free or combined; in cast iron as well as in steel, the effect of graphite was second to that of the carbide commonly known as fixed or combined carbon.

Beyond a certain degree of purity, as in wrought iron and carbon steels, the treatment as to annealing and tempering became of first importance. The magnetic properties of some of the alloys of iron, nickel, or manganese were such as to show that the physical structure was the ultimate determining factor. The hysteresis loss was in general inversely as the degree of purity; but in comparatively pure irons it was determined principally by its treatment as to annealing, heating, and mechanical straining.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**(To-day) FRIDAY, May 22nd.**

PHYSICAL SOCIETY.

*5 p.m.* Meeting at Burlington House. Adjourned discussion on Messrs. Frith and Rodgers' Paper: "On the True Resistance of the Electric Arc." The following Papers will be read: (1) "On Dielectrics," by R. Appleyard; (2) "The Field of an Elliptical Current," by J. Viriamu Jones; (3) "An Instrument to measure Frequency," by A. Campbell.

INSTITUTION OF ELECTRICAL ENGINEERS.

*8 p.m.* Students' Meeting at 25, Great George-street, S.W. Paper to be read: "The X-Ray Photography," by H. S. Tyson-Wolff.

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Hysteresis," by Prof. J. A. Ewing, F.R.S.

**THURSDAY, May 28th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*8 p.m.* Ordinary General Meeting. Paper to be read: "The Utilisation of Water Power, especially with a small Fall, with some examples of Plants for the Generation of Electrical Energy," by Sept. Stoiger.

* Unless the ratio of the maximum of the fundamental to the maximum of the harmonic is greater than the ratio of their wave-lengths, the curve will dip below the zero line at the ends of the half-period, in cases such as shown in $x$, Fig. 15.

* [For an illustrated description of this instrument see *The Electrician*, May 8, 1896, p. 41.—ED. *E.*]

## WAVE-FORMS AND IRON LOSSES.

Those who have watched the progress of alternate-current theory during the past few years will have observed, and probably have been pleased to see, that greater importance has been attached to actual physical research and less to abstract mathematical deductions. In the early days of this branch of electro-technical science we were commonly treated to a pound of abstract analysis, based upon FOURIER'S theorem, to every short ounce of actual experiment. True enough, tests were made, and the efficiencies of the various forms of alternate-current apparatus were measured and served up in tabular form. But these departures from pure abstractions were more in the nature of engineering metering than physical measurement, and in most cases they served only to intensify the gap between the so-called theory and what was found to occur in actual work. Sine waves and simple harmonic functions were the mathematical bricks and mortar of the theorist of that day, and if our results in practice did not resemble the structure which was reared of these materials, so much the worse, we were told, for our results in practice.

In those days of guessing by equation, alternate-current waves of complicated form were known and recognised by theorists; but the acquaintance was of a distant and frigid nature, and warm affection was reserved alone for the pure and genuine sine. Within the very heart of the alternator, it was true, all sorts of complicated waves might occur; but when the terminals were reached most of the harmonics would have suffered extinction; while by the time the energy had filtered through a system of transformers, not one single harmonic would have been able to survive the ordeal of self-induction, and nothing but a "true sine wave" would appear at the distant secondary end. FOURIER'S theorem showed it;

Digitized by Google

and at the magic of that name everyone bowed in acquiescence; and no one took the trouble to find whether the wave was or was not really a simple sine.

Gradually, however, the hardy vitality of a complicated wave-form came to be recognised, and it was found to be one of the most difficult, not one of the easiest things, to effect an appreciable change in a wave-form impressed upon a circuit by an alternator or set of alternators. Transformers, Dr. Fleming has recently told us, copy every minor ripple and tiny harmonic with the greatest accuracy and faithfulness. The conditions under which the form of a supply-system wave becomes simplified occur not commonly but rarely, in general practice. So that the important question arose: What are the relative commercial values of the different forms of waves that are met with in practice? We believe that this question was first raised in America, where the practical engineer, bombarded by a superabundance of equation-woven "theory," had grown tired of it all and had struck out for himself on practical lines. Unfortunately a section of American engineers still laboured under the-thrall of misapplied mathematics; and when these found that alternators of various kinds did not have their waves twisted into true sines, they obeyed the dictates of the theorists and tried to build their alternators to generate waves of this simple form. Whatever may be said for the simple sine wave purely in relation to line-drop over long-distance transmission circuits, there was nothing at that time and there is nothing now to show that the pure and simple sine is the most efficient and best form for alternators in general. In fact, it is demonstrably not the best form. We were therefore led to raise a protest against this obviously hasty and unwarranted inference from "theory" in our issue of July 6, 1894.

Awakened thus to the importance of the question of alternator wave-form, electrical engineers on both sides of the Atlantic busily engaged themselves in solving the many problems that it suggested. After the war of words had ceased which immediately followed our criticism of the American practice just referred to, a great deal of experimental work was commenced, some of the results of which have only just been published in the admirable Paper that Messrs. Beeton, Taylor and Barr read last Thursday week before the Institution of Electrical Engineers. We commenced a reprint of this contribution to the literature of the subject in our last issue and complete it this week. But we are anticipating the order of events somewhat, and must return to an earlier stage, when, on July 6, 1895, a Paper on "The Behaviour of Transformers under the Influence of Alternating Currents of Different Wave-Forms" was read by Dr. G. Rössler at the Münich meeting of the Verband Deutscher Electrotechniker We give the actual date of this meeting in order that Dr. Rössler's important work may be properly acknowledged and that a legitimate place may be assigned to it in the history of the subject. A translation of this valuable Paper was commenced in our columns on November 22, 1895.

The researches of Dr. Rössler, and the later researches of Dr. Fleming and others, were carried on by the aid of a number of actual alternators giving different types of waves. It will be evident that though by this means it would be possible to determine in which direction a general improvement of wave form might be effected, the limited number and the limitations in form of the available waves would make it impossible to deduce any general quantitative law. A valuable step in advance was made when it occurred to the authors of the Paper just read before the Institution of Electrical Engineers, to produce artificial and carefully selected distortions in the wave of a single alternator, by "injecting" resistance and capacity into the circuit at definite parts of the wave and for definite intervals. The perfect control thus acquired over the wave-form experimented upon enabled a quantitative series of results to be determined, from which not only the best form of wave but the degree of its superiority over any other form could be accurately ascertained.

The discussion on Messrs. Beeton, Taylor and Barr's Paper revealed that electrical engineers in this country are not wholly alive to the importance of the question at issue, and are divided as to its practical value. Dr. Fleming, whose own work on the subject has been neither small nor unimportant, was the first to speak. He paid a tribute to the ingenuity of the authors' method of producing their wave-forms, but pointed out that transformer design is more than a matter of minimising iron loss, and reminded his hearers that a peaked form of wave produces, for a given voltmeter reading, a greater stress on the insulation of the circuit than less efficient forms. Dr. Rössler has observed this too, but has qualified his observation by the remark that "with a suitable form of wave of this type one could remove most of the objections based on the higher insulation required, without otherwise affecting the properties of these (peaked) waves." Mr. Evershed followed with some arithmetic. From Mr. Evershed, who is an avowed opponent of pure theory, one naturally expected to get practical arithmetic. He told us that the iron losses in a transformer amounted to only 2·5 per cent., and that 10 per cent. of this was nothing, or nothing worth making a fuss about, and not worth the trouble of saving; and that when it was saved it was only the cost of the coal and the oil that was really saved. Mr. Evershed's figures disappointed us, because they were not practical, but were based on assumptions that do not correspond to practice. A transformer doubtless may be designed that, when always kept on full load and under laboratory conditions, will have an iron loss not greater than 2·5 per cent. But when that same excellent transformer is put into active commission on a supply network, it will have to work at very much lower loads, while all the time wasting in its iron exactly the same amount of power as before. At one-tenth of its best load, this transformer would waste no less than 25 per cent. of the energy supplied to it. The contention cannot be upheld that on any transformer system, however carefully banked, the transformers can be run all day and night long on their best load; while on the vast majority of systems, where no banking regulation is even attempted, the average load throughout the year cannot be anything but a small fraction of the most efficient load. Mr. Evershed's estimate of a total transformer capacity of 4 million units, for a system delivering 3 million units per annum to the consumers, is very far below the actual mark, as will be seen when we say that it represents a transformer load factor of 75 per cent. for the entire year. The statistics of alternate current supply systems speak for themselves, and quite justify our contention that to effect a 10 per cent. reduction in transformer losses is a matter of more than academic interest. Newcastle with its 40 per cent. loss in distribution, Sheffield with its 30 per cent. loss, or even Bedford—the most favourable example we can cite—with more than 10 per cent. of distribution loss, shows that there is economy of a very valuable magnitude yet to be effected in this direction. We are not contending that all this loss takes place in the transformers, nor that more than a small percentage of it could be saved by means of a better wave-form. What we do assert is that the saving to be effected is much greater than Mr. Evershed would have us believe, and sufficiently large to merit the attention of practical engineers.

Digitized by Google

In quite another respect, also, do we differ from Mr. EVERSHED. Doubtless it is true, as Dr. FLEMING has observed, that all engineering design is a matter of compromise. But it is equally true that the best design arises from the most intelligent of all possible compromises; and a design is most intelligent when the engineer is in possession of the greatest number of facts about what he intends to do. He cannot design intelligently and work in the dark at the same time, and even partial darkness is injurious to good work. Now, the suggestion that any element of design is trivial and insignificant amounts to a statement that it can be ignored. And if one such supposed trifle may be ignored so may many others. If we can afford to be careless about alternator wave-form, because, as Mr. EVERSHED asserts, it makes a difference of only £42 per annum in the working expenses, we can also afford to be careless about the length of a shaft bearing, or the choice of a lubricating oil, or the selection of station ammeters and voltmeters. The Scotch say, "many a mickle makes a muckle," and there is a sound principle of engineering design in the old-fashioned English proverb that "if we take care of the pence, the pounds will take care of themselves." Besides, how, unless we investigate the matter in the way Mr. BEETON and his colleagues have done, can we be sure that the most efficient type of wave-form is not given by the cheapest design of alternator? Those who scoff at the matter tacitly assume that it must be the dearest.

## REVIEWS.

**The Magnetic Circuit in Theory and Practice.** By Dr. H. DU BOIS. Translated by Dr. Atkinson. (London: Longmans, Green and Co. 1896.)

The accomplished translator of Ganot has done another service to English students of science—this time to a later generation—by putting within their easier reach Dr. du Bois' treatise on the magnetic circuit, originally published in German two years ago. The translation has had the advantage of the author's own revision, and is enriched by a number of notes, in which he has made brief reference to some of the most recent developments of his subject. Though here and there a trace of the German idiom survives, Dr. Atkinson has done his work well, and has left Dr. du Bois' English friends comparatively little reason for regretting that the author did not select English, instead of German, as his original medium of expression, out of the many European languages of which he is master.

Amongst modern advances in the science of magnetism the conception of the magnetic circuit has taken a leading place. Compared with older methods of attacking magnetic problems it offers an alternative which is always interesting, and often in the highest degree fruitful. Many cases, and especially cases such as arise in dynamo design, admit of satisfactory treatment by aid of this idea, when they are too complex for solution in any other way.

Its utility is so great and its range of application so wide, that there would have been matter of surprise if it had not received the cordial welcome which electricians have, in fact, given it. Small wonder, indeed, that in the warmth of their reception some of them perhaps allowed their enthusiasm to get the better of their judgment. Most remarkable opinions were expressed as to the influence of the new ideas in displacing the old ones. The conception of magnetic poles, the law of inverse squares, and so on, were to be completely shelved. We were gravely told that it was impossible now to gauge how much the progress of electrical science had been "impeded and retarded" by the weight of the great names of Coulomb and Poisson and Laplace. The notion of the magnetic circuit was for electrical engineers the pearl of great price; to gain it they were to sell all they had formerly held dear. "Having this, they need no laws of inverse squares of distances, no magnetic moments, none of the elaborate expressions for surface distribution of magnetism, none of the ancient paraphernalia of the last century." It was almost the language of the revivalist preacher; but the new gospel of the magnetic circuit fortunately had enough real strength and vitality to survive even such excesses on the part of its more ardent proselytes.

Dr. du Bois gives no countenance whatever to any such extravagant views. He is studiously careful to assign to the notion of the magnetic circuit its proper place both in magnetic theory and in the application of theory. He recognises at once its value and its limitations, and we nowhere find him playing the part of the child who shows its devotion to a new toy by throwing the old ones into the dust-bin.

One of the most interesting chapters of his book is that which gives a historical survey of the development of this important conception. The analogy of magnetic systems to circuits of other kinds is in fact so old that if all the "ancient paraphernalia of the last century" were swept away the foundations of this analogy would perish with them. Dr. du Bois traces it as far back as Euler. In the hands of Faraday, of Kelvin, and of Maxwell it took clearer shape, Maxwell's contribution dealing especially with the analogy to the electric circuit, and Lord Kelvin with the analogy to the conduction of heat and the flow of fluid through porous material. It was this hydro-kinetic analogy that led Lord Kelvin to introduce the word permeability, now so familiar to everyone who has to speak of the magnetic quality of iron. Coming to more recent developments, Dr. du Bois refers to the writings of Rowland, Bosanquet and W. von Siemens, to the practical work of Elphinstone and Vincent and of Kapp, all of which may be said to have prepared the way for the great Paper in which J. and E. Hopkinson gave definite scientific expression to ideas which had up to then been too general to be very useful, or too vague to be very convincing. It is not too much to say that this Paper was to most students of magnetism the first evidence that the idea of the magnetic circuit could in certain cases be sufficiently divested of arbitrary assumptions to be logically conclusive, and at the same time be applied to practical problems with admirable effect. It is essentially from the standpoint supplied by this Paper that Dr. du Bois has written his book.

He writes with the fullest knowledge of his subject, both in its mathematical and its experimental aspect. The treatment is conspicuously thorough and exact. Dr. du Bois assumes some knowledge of the magnetic qualities of materials, that is to say, he is content to refer students to other works where such results have been fully stated. The book is not one for beginners in magnetism; it is a critical and philosophical study of a large part of magnetic theory and of a large group of methods in magnetic investigation. The field is one in which Dr. du Bois is himself well known as an original worker. Amongst the experiments and experimental methods that are described a considerable number are the author's own. If anything, he has given these a less prominent place than they deserve; but in dealing with the work of other investigators his book shows, in every chapter, how wide has been his reading and how careful and sympathetic his appreciation of the experiments of his contemporaries. There is a wealth of reference to the work of others throughout the volume that is not very often found in English text books, for we are apt, most of us, to go our own way without looking much to the right or left, and scarcely ever glancing behind.

It would be impossible without unduly extending this notice to give even a summary of the large field of which the work treats. The first five chapters deal with mathematic theory, tempered of course by experiment; then come applications, history, and accounts of experimental methods. No existing text book or treatise covers the same ground. The book is in all respects one to be commended to the attention of those who wish to obtain a real grasp of magnetic science. The present writer may perhaps be allowed to express a hope that those who have found a certain volume on magnetic induction serviceable to them will enlarge their knowledge by reading Dr. du Bois.

Digitized by Google

English readers may perhaps regret that the "magnetic force" with which they are familiar is called by Dr. du Bois the "magnetic intensity," or more generally the "intensity" alone. We find such phrases as "lines of intensity" and "the direction of the intensity." Dr. du Bois is perfectly consistent in his nomenclature, and it is not likely that any confusion will be caused. But these things are matters of taste and habit, and (especially in view of the usage which gives to the quantity **I** the name of intensity of magnetisation) we should have preferred to see the name magnetic force retained for **H**.

This, however, is a small point, in no way diminishing the obligation under which Dr. du Bois has put students of physical science and electro-technics. He has given them a systematic and authoritative account of modern ideas in magnetism. J. A. E.

## STEEL STEAM PIPES AND FITTINGS, AND BERNARDOS ARC WELDING IN CONNECTION THEREWITH.*

BY SAMUEL M'CARTHY.

The constantly increasing use of steam at high pressures, both for marine and land engines, renders the employment of the most suitable and reliable steam pipes a matter of the utmost importance and interest to engineers; and it is somewhat surprising that the subject does not appear to have been brought before this Institution for consideration and discussion during so long a period.

*Cast-iron and Copper Pipes.*—Cast iron, which has the advantage of being seamless, and which can be moulded into any desired shape, is heavy, cumbrous, frequently porous, and always liable to fracture by a blow. The necessarily great thickness of cast-iron steam-pipes, and the rigidity of the bends, also add greatly to the difficulties of arranging for expansion. Hence the use of this material for pressures over 50lb. or 60lb. per square inch is becoming more and more rare. Copper, which for so long a period was almost exclusively adopted in the navy, and also to a great extent in the mercantile marine, for steam and feed-pipes, has, in consequence of numerous disastrous failures, become of late years greatly discredited. The cause of its failure need not be entered into here, nasmuch as the subject was fully dealt with in the Paper on steam-pipes which was read by Mr. J. T. Milton before the Institution of Naval Architects in April, 1895 (*Transactions*, Vol. XXXVI. p. 191).

*Wrought-Iron and Steel Pipes.*—Cast-iron and copper having failed to afford the necessary security and confidence in connection with steam at high pressures, there arose a great demand for welded wrought-iron or steel pipes, which was promptly met by the leading tube-makers, who lost no time in procuring the requisite machinery for their manufacture. With regard to the respective merits of iron and steel for this purpose, as for many others, there has always been a great difference of opinion among engineers; and the controversy is not yet at an end, but invites renewed experiment and useful discussion. In the early days of the manufacture of large welded steam-pipes, iron was most frequently preferred; and doubtless the preference was then wise, and was justified by experience, inasmuch as at that time the manufacture of steel plates had not reached the degree of perfection to which it has since attained. Not only were the steel plates often laminated and blistered, but it was difficult to procure mild steel of a suitable quality for welding. Happily these troubles have to a great extent disappeared; and an abundance of excellent mild steel can be obtained, which can be welded as readily as iron.

*Corrosion.*—One of the principal objections raised by the opponents of steel has been that it is more subject to corrosion than iron; and doubtless this would be a grave defect if shown by experience to prevail. This matter was dealt with at great length in the Paper on the comparative endurance of iron and mild steel when exposed to corrosive influences, which was read by Mr. David Phillips before the Institution of Civil Engineers in March, 1881 (*Proceedings*, Vol. LXV. p. 73). As the result of numerous experiments, he came to the conclusion that steel, in the form either of boiler tubes or of plates, was greatly inferior to iron in power to resist corrosion; but in the lengthened discussion which followed the speakers were almost unanimous in their dissent from this conclusion. At all events, whatever may be the result as regards boiler tubes, there is every reason to believe that welded steel steam-pipes are free from any risk in this respect. Recently the author has had an opportunity of examining several lengths of 7in. steam-pipes and bends, made of steel, at the City of London electric lighting station at Bankside, which have been constantly at work at a pressure of 160lb. for over three years, and which exhibit not the slightest appearance of pitting, scoring, or corrosion in any form. Although only an isolated case, this affords pretty strong evidence so far as it goes; and the author has never heard of a single complaint as regards corrosion of steel, steam-pipes in connection with the large quantities which have been supplied. In erecting ranges of steam-pipes, great care should be taken to ensure efficient drainage; for should there be any point in the range where the condensed water is allowed to lodge, corrosion will no doubt take place sooner or later at that part, whether the pipes are made of wrought iron or of steel.

*Thickness of Metal.*—As to the comparative thickness of steel and iron pipes, it might naturally be expected that the former would be made lighter in proportion to the greater tensile strength of steel. Theoretically this should be so; but in practice it is carried out to only a limited extent. Not only is a large margin required for safety, but the exigencies of manufacture necessitate a certain thickness of plate to ensure making a sound weld; and this thickness cannot be reduced without risk. For instance, a common size of steam-pipe, 10in. bore, is most conveniently made of $\frac{1}{4}$in. plate, which would be amply strong enough for iron, and is consequently excessive for steel; but the reduction of $\frac{1}{16}$in. in the thickness would affect the cost and the weight so slightly, that it is thought best to err on the safe side. For larger sizes, of 12in. to 18in. bore, it is found practicable to make steel pipes somewhat lighter in proportion to iron. In this connection it is interesting to note that the Admiralty are now using steel for all sizes of steam-pipes over 2in. bore. Above 9in. bore they still adhere to the practice of having a butt strap or cover strip riveted along the line of weld, which the author believes to be worse than useless, as the numerous rivet-holes necessarily tend to weaken the pipe. It is also probable that the presence of the cover strip, in connection with the expansion of the pipe both circumferentially and longitudinally, has the effect of setting up a tearing strain, which may result in leakage at the rivets. The addition of the butt strap also adds greatly to the cost of the pipes. In a recent specification for steam-pipes the Admiralty fix $\frac{5}{8}$ths of an inch as the uniform thickness for all pipes from 6in. to 14in. diameter of bore, the tensile strength of the steel not to exceed 25 tons, and not to be less than 23 tons per square inch. In the following Table I. are given the thicknesses which are usually specified for steam pipes from 6in. up to 18in. bore, for pressures varying from 100lb. to 180lb. per square inch, also the corresponding hydraulic test pressures. In addition to the hydraulic test, the pipes are also tested with high-pressure steam. This is important, because they are thus tested under actual working conditions as regards temperature and consequent expansion; and any minute pin-hole which has not been revealed by the cold-water test is certain to be detected under steam.

**Table I.**—*Thicknesses of Steel Steam Pipes for varying pressures.*

| Diameter of bore. | Steam pressure, pounds per square inch. 100 | 120 | 150 | 180 |

*Methods of Manufacture.*—It is frequently supposed that the electric arc is brought into operation for welding the longitudinal seam of the barrel of the pipe. As a matter of fact this is not the case. It can of course, be done, and has been done successfully in many instances: but as it was found from experience that no saving in cost was effected, and that nothing was gained either in speed or in efficiency by the use of electricity for this purpose, the straight seams are still welded in the ordinary manner, namely, either in the rolls or by gas and power.

*Roll Welding.*—In this process the iron or steel in the shape of strip is first scarfed along both edges in a planing machine, on the outer face along one edge, and on the inner face along the other; it is then heated in a muffle, and, by being drawn through skelping dies, is bent into tubular form or skelp, and is ready for the welding furnace. When the welding heat is reached the skelp is withdrawn from the furnace with tongs, as shown full size in Fig. 1, and the end is placed upon the head of a horizontal mandril fixed

* Paper read before the Institution of Mechanical Engineers.

Digitized by Google

to a long rod, which is held between a pair of revolving rolls that are turned to suit the particular size of tube being made. The skelp being seized by the rolls is rapidly welded by the pressure exerted upon it between the two rolls on the outside and the mandril on the inside of the tube. In all cases the tube is drawn twice through the rolls at a welding heat, the process being the same each time. On finally leaving the welding rolls, the tube passes through a mangle or reeling machine, which straightens it; the ends are then cut off square, and it is ready for testing.

*Gas Welding.*—The strips, after being scarfed along their edges, are heated only cherry red in a muffle, and are then bent to the required diameter in the rolls. The pipe is next placed on a "beak," as shown half full-size in Figs. 2 and 3, and a jet of gas is brought to bear along the seam, whereby in a short time, varying according to the thickness of the plate, a length of about 6in. to 8in. is brought to a welding heat. A small quick-speed steam hammer, fixed above the work, then rapidly closes the seam, and completes the weld. The operation is repeated on the next length,

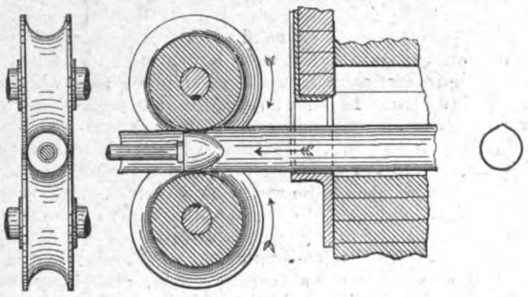

FIG. 1.—Roll Welding.

until the longitudinal seam is completed. The use of gas renders the process clean, and absolutely free from dust and other impurities; and the edges of the pipe, having been carefully freed from scale after leaving the heating furnace and rolls, a perfectly sound weld is obtained. At some works all sizes of pipes are made through the roll, while at others this method is followed only up to 8in. bore, and all the larger sizes are welded by gas.

*Bernardos Arc Welding.*—It is in the manufacture and attachment of flanges, branches, bends and T- pieces that the Bernardos system of welding by means of the electric arc plays such an

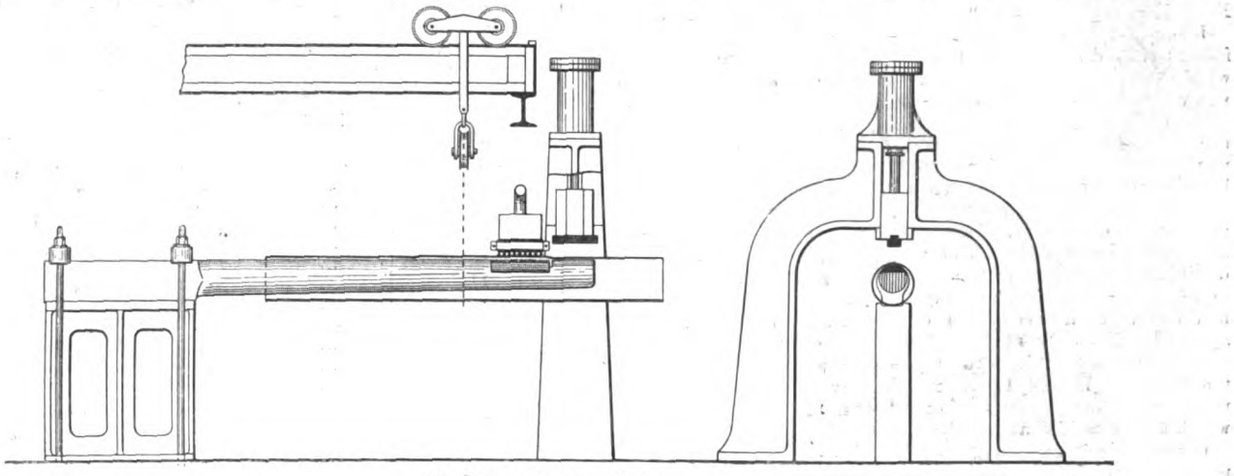

FIG. 2 and 3.—Gas Welding.

important part. This process has now been in constant operation for over five years at Messrs. Lloyd and Lloyd's Coombs Wood Works, near Halesowen, with which the author is connected, where during this period it has been employed chiefly on large steel pipes and connections, suitable for high-pressure steam. The process has been so fully and clearly described from time to time in the various technical and scientific journals that it is unnecessary to do more than briefly illustrate it here, before showing its special application in connection with the subject of the present Paper. The method of working is simple. Ordinary low-tension continuous-current lighting dynamos are used; to the terminals of these a battery of Bernados accumulators is connected, into which the current flows continuously. When the welding circuit is closed, the current flows from the dynamos and accumulators, and large resistances are used when necessary. In this way a large discharge is obtained, equal to about twice the capacity of the dynamos, and the load factor of the apparatus is high. For some purposes it is possible to work without the accumulators; but when this is done the efficiency of the apparatus is not so high, because during part of the working period no current whatever is passing, and the machinery is running light.

As illustrated by the diagram, Fig. 4, the plant is run on the parallel system, and between the terminals of the dynamos or battery as many welding arcs can be connected as may be desired,

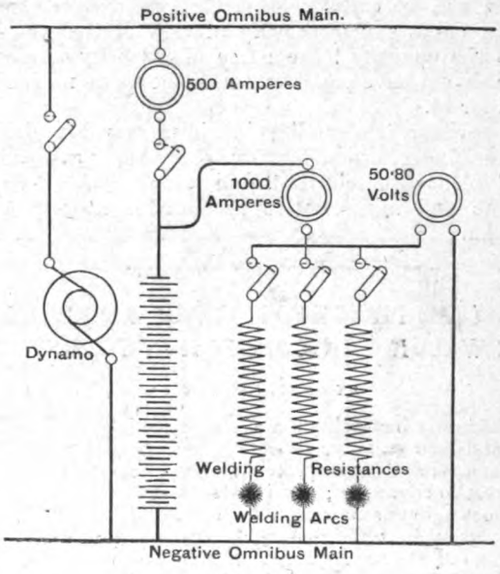

FIG. 4.

and every welder is able, independently of the others, to vary his own current to suit the work in hand at the moment. One terminal of the circuit is connected by means of a flexible cable to a carbon pencil in an insulated holder (Fig. 5), which is held by the workman; the other terminal is connected to the table on which the work lies, or to the work itself. When iron or steel is under treatment, itis usual to make the carbon the negative pole, and the iron or steel the positive pole; but for other metals the poles are sometimes reversed. In the appendix is given a summary of the results of experiments made by Messrs. David Kirkaldy and Son for Messrs. Lloyd and Lloyd, to ascertain the tensile strength of electric-welded bars of various brands and sizes; and also a comparison of these with fire-welded bars.

*Flanges.*—The method usually adopted for welding flanges to steam pipes is as follows (Figs. 6 to 11). The flange is stamped out under the steam hammer in such a way that a V-shaped groove is left on the inside edge, as shown double full size in Fig. 7, extending about three-fourths through the thickness of the metal. The flange is next shrunk upon the tube, with the flat face outwards or at the end of the tube, and is carefully set in the exact position required (Fig. 8). The welding consists in laying small pieces of steel in the V-shaped groove, and welding them in one by one by means of the electric arc, Fig. 8, the welds being freely hammered between each heat. The welder makes a complete circuit of the back of the flange, and fills it up sufficiently to make a fillet of about 1½in. radius, Fig. 9. In this way the flange is solidly welded to the tube at the back, and about three-fourths of the way through its thickness, Fig. 9; but the front or outer side

Digitized by Google

s not yet welded. The tube is then up-ended, Fig. 10, and the outer side of the flange is welded to the tube, the only difference being that the heat of the arc is used to burn out a cavity all round the junction of the pipe and the flange, until the depth is reached at which the two have already been united ; this cavity is then welded up, Fig. 11, in the same way as the back of the flange, thus ensuring that the flarge is welded solid to the pipe right through.

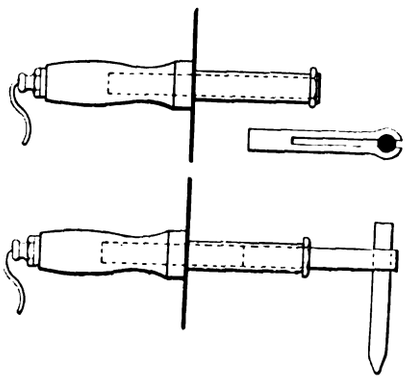

Fig. 5.—Electric Carbon Holder.

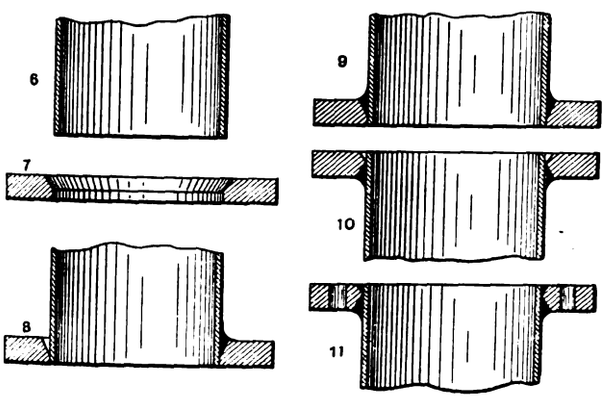
*Outlets, Branches and T-pieces.*—The welding in of outlets and branches into steam-tubes is done by much the same method as already described in the case of the flanges. The outlet, which consists of a piece of ordinary lap-welded tube, is cut off to the required length, and a hole is burnt by the arc in the tube, large enough for the outlet just to fit into. When fixed in the right



Figs. 6 to 11.—Flange Welding.

position the outlet is welded in, as in the case of the flange, by laying on small pieces of steel about 1in. long by $\frac{3}{4}$in. wide and $\frac{1}{4}$in. thick, and welding them in one by one, continuing the process all round the outlet, until a fillet is formed of about $1\frac{1}{2}$in. radius, but this varies slightly with the position of the outlet on the tube. A T-piece is made in a precisely similar way, a short piece of tube

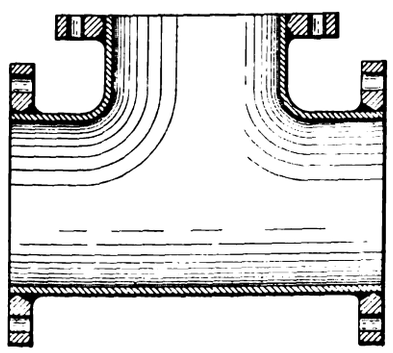


Fig. 12.—Tee-Piece.

being welded into a longer piece (Fig. 12) ; and a cross (Fig. 13) is made by welding two similar short pieces, one on either side of the main tube.

*Bends and Expansion Pipes.*—These are made by the same method as the outlets and T-pieces. In Fig. 14 is shown a form of expansion bend, of which a number are at work, and are found highly effective.

*Length and Size of Arc.*—One point in connection with electric-welded work, to which the author would call special attention, is the length and size of the arc which is used in the welding of various kinds of work. With a short arc, the carbon point is brought down too close to the steel ; and the result is inferior work, not only from the presence of the carbon, but also because the heat is concentrated upon so small a surface that the strains set up in cooling are considerable. The longer the arc, the softer and more diffused is the heat ; and any slight strain which may be set up can be got rid of by careful annealing. A long arc is therefore indispensable to the proper working of the system.

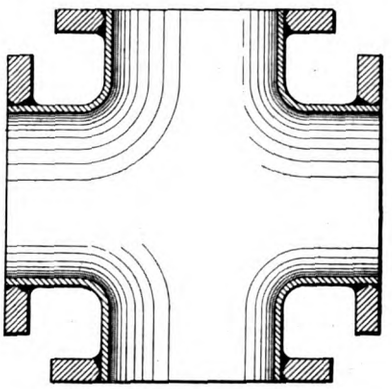

Fig. 13.—Cross-Piece.

*Strength of Electric-welded Flanges.*—An 8in. iron pipe $\frac{1}{4}$in. thick, with flanges electrically welded on, when tested to destruction at Lloyd's Proving House, Netherton, broke in the body of the pipe at over 88 tons, the welded part remaining intact ; and a similar pipe of steel broke in the welded part of the flange at over 101 tons. These tests were tensile only, and were carried out with the view of proving the absolute soundness and consequent strength of the flanges electrically welded on. For this purpose special tackle was made. A blank flange with an eye-bolt attached was secured to each flange of the pipe, and the chain of the testing machine was connected with the eye-bolts at each end, with the result given above.

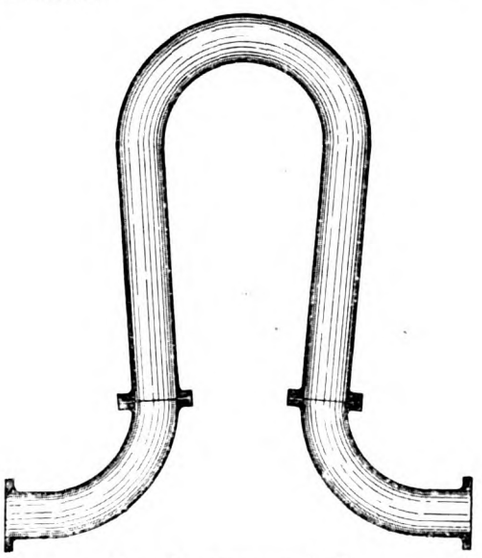

Fig. 14.—Expansion Bend.

*Other Applications of Arc Welding.*—All kinds of work of the above description can be readily and satisfactorily done by this process ; but its utility in large works does not stop here. Small flanges can be heated and welded upon tubes by spinning them in a lathe at a high speed, and allowing the arc to play on them, the weld being made by the pressure of two rollers, one inside and the other outside the tube. Defects in steel castings and in finished forgings can be repaired with the greatest ease ; and the fact that, when such repaired articles are faced or turned in the lathe, the turnings come away sound and whole, is a proof that the welding has been perfect, and that the metal has not been burnt or rendered brittle by the process.

Reverting to steam pipes with flanges and outlets electrically-welded on, these have been in constant request ever since the Benardos system was introduced into this country some five and

Digitized by Google

a-half years ago by Mr. Henry Howard, and the electric welding department at Messrs. Lloyd and Lloyd's Coombs Wood Works has been kept going almost night and day. The principal demand has come from the various electric lighting works, for which the advantage and security were at once recognised of the solid welded flange, and also of the reduction in the number of joints by the outlets being welded to the tube. In many instances also the bend and the tube have been made in one piece, thus further reducing the joints. The City of London electric lighting station at Bankside has been almost entirely fitted with these pipes. They are also adopted at the Metropolitan electric lighting station at Amberley-road, the Kensington and Knightsbridge, the Bristol and the Nottingham electric lighting stations, and many others. Among users of these pipes and fittings in connection with high-pressure steam engines may be mentioned Messrs. Pearson and Sons, Blackwall Tunnel Works; Messrs. J. Musgrave and Sons, Bolton; Sir Titus Salt, Bart., Sons and Co., Saltaire; and many others.

*Joints.*—In connection with the cognate subject of joints, the author is enabled by the kindness of Mr. Frank Bailey to describe a simple form of joint in use at the City of London and the Metropolitan electric lighting stations, which in conjunction with the solid electrically welded flanges has given excellent results. As shown double full size in Fig. 15, the joint is made simply with a copper ring $\frac{1}{8}$in. thick, of which a specimen is exhibited. These rings are cut of the required thickness from a copper cylinder of the necessary size, and are carefully annealed. The great thickness of the solid welded flanges admits of their being screwed tightly together, without any possibility of springing; and an absolutely steam-tight and durable joint is thereby made, which gives no trouble whatever.

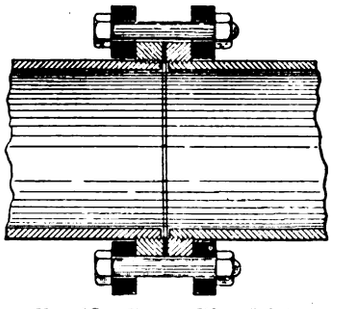

Fig. 15. Copper Ring Joint.

*Bolt Holes.*—Another great advantage of the solid welded flange is that it obviates any difficulty with the bolt holes. The frequent trouble and annoyance experienced with screwed flanges, from the bolt holes not coming fair opposite each other, are well known; and the objections to flanges riveted on steam pipes are too obvious to need any comment.

## Appendix.

In Table II. is given a summary of experiments to ascertain the tensile strength, contraction of area and extension of electrically-welded bars of Lowmoor iron, Parkgate steel, Farnley iron and Netherton crown best iron; ten bars were tested of each of the five sizes, named, and the mean results are here recorded of the ten welded and the ten solid bars of each size. All the welds were scarf, the length of scarf averaging 1$\frac{1}{4}$in. to 1$\frac{1}{2}$in. The results obtained from the welds of Lowmoor iron, Parkgate steel and Farnley iron are satisfactory; the principal features are absence of cinder or impurities from the faces of the scarf, and the maintenance a fair amount of ductily at the weld, the material not being abnormally affected by the heating. Where the welds have come out low, the appearance of the fracture points either to the metal having not been hot enough, or to the thin edge of the scarf having cooled before the weld was closed by hammering. In the welds of the Netherton iron there is a serious tendency to loss of ductility, the fractures showing crystalline. As, however, there are some good welds amongst them without these objections, it would appear as if the treatment, as regards the amount of heat, had not been adapted to the nature of the iron. In order to judge of the full merits and capabilities of the electric welding, due regard must be paid to the individual results as well as to the average. The mean results in Table II. are based upon the whole of the ten welds, as far as the ultimate stress and the ratio of weld to solid are concerned; but as regards the contraction of area and the extension, the results are the mean of the bars which broke through the weld, because necessarily, where the weld did not break, the contraction and the ultimate extension could not be obtained.

In Table III. is given a summary of experiments to ascertain the tensile strength, contraction of area, and extension of fire-welded bars, of different sizes of the foregoing brands, welded by engineers' smiths; and also a comparison with the electrically welded bars. The general average of the electrically-heated welds is seen to be 18$\frac{1}{2}$ per cent. better in figure of merit than that of the fire-heated welds. The welding of the fire-heated iron bars was well done, the difference being slight compared with the same sizes heated electrically; but turning to the steel, the fire-heated welds are more irregular or uncertain, some being good and others bad.

**Table II.**—*Mean Results of Tests of Electric-Welded Bars.*

| Brand. | Nominal size. | Fracture through solid or weld. | Ultimate tensile strength per sq. inch. T | Contraction of area at fracture. C. | Extension in 10in. | Tensile strength, ratio of weld to solid. |
|---|---|---|---|---|---|---|
| | Inches. | | Lb. Tons. | Per cent. | Per cent. | Per cent. |
| Lowmoor iron | 5 × $\frac{3}{16}$ | Solid | 58,417 = 26·1 | 42·3 | 19·5 | |
| | | Weld | 47,367 = 21·1 | 17·3 | 7·3 | 81·1 |
| | 2 × $\frac{1}{4}$ | Solid | 55,537 = 24·8 | 45·7 | 22·9 | |
| | | Weld | 48,429 = 21·6 | 20·9 | 8·1 | 8·72 |
| | 2 × $\frac{5}{16}$ | Solid | 53,237 = 23·8 | 46·0 | 24·1 | |
| | | Weld | 48,890 = 21·8 | 20·7 | 9·7 | 91·8 |
| | 2 × $\frac{3}{8}$ | Solid | 55,363 = 24·7 | 41·7 | 26·7 | |
| | | Weld | 49,517 = 22·1 | 16·7 | 9·0 | 89·4 |

## DISCUSSION.

Mr. McCARTHY, before the discussion was started, called attention to the specimens of tubes exhibited. One piece of tube had been left unfinished purposely to show the process, and he thought the specimens would speak for themselves. They were of steel and all electrically welded precisely in the manner which had been described in the Paper, and on the diagrams on the wall. He would like to call attention to the importance of using the very best steel pipes.

Mr. SCHONHEYDER said he had not examined the specimens on the table, but it seemed to him that according to the process there must be a rough corner inside a bend where the weld has taken place, and not as shown on the drawings 12 and 13. He thought it was a disadvantage, but perhaps the author would explain that it is possible to expand them out and make the corners more as they usually are

Digitized by Google

Mr. DRUITT HALPIN said he would like to call attention to a point in connection with Fig. 15. He showed a drawing of a joint made by the late Mr. Willans, and thought it had great advantages over the joint shown. This consisted in a copper ring placed between the flanges, the pipes being bolted through the flanges. He had used a great many hundreds of these joints, and had only had one case of leakage.

Mr. HOWELL said as he had had a great deal of experience in welding tubes, it might not be out of place for him to say a few words on the subject. He had read the Paper, and the description of the electric welding. He should not call it welding at all, but electric *soldering*, because the metal which is set to be welded in is not really welded, but fused in. The effect of this, he said, was that there was a great liability of the steel at the root of the flange, in the immediate neighbourhood of the weld, becoming reduced in quality, and getting more brittle than the remainder of the tube. In 1892 he went into the question of welding, and took a piece of tube of a suitable length, and cut it into rings 2in. long, of which there were 28. The first ring was cut open in the weld, and the next ring was cut in the centre opposite the weld. They were taken in pairs along the whole length of the tube. This was done for the purpose of testing the strength of the weld in comparison with the solid portion of the tube side by side. Six out of the 14 did not break in the weld at all, but it would be useless for him to go into the whole of the tests. The tensile strength of the solid was 22·71 tons, and that of the weld 22·58, or very nearly as strong as the solid itself. Since he had received the advance copy of the Paper, he had hurriedly made a few tests similar to those mentioned in the Paper. The elongation was 18·8 per cent., and in the weld actually 21·50 per cent., showing that in this case the elongation was greater than it was in the solid, and he might say that this weld did not break at all, but the tube broke in the solid. From what he had learned from these experiments he did not think electric welding was as good as gas or roll welding. The great advantage with electric welding was that you could weld small pieces of tube, and this was very difficult to do with gas, because you could not easily get at them.

Mr. PLATT said he would like to ask Mr. McCarthy why he places the copper ring in a joint so that it is not flush with the inside of the pipe. He also wanted to know why pipes were welded at all when you could make perfect pipes out of the solid. There were seamless pipes being made in London up to 12in. diameter, 12ft. long and ¼in. thick, and they were being largely used by the Admiralty, and he thought it a very much safer job than any welded pipe could be. Some members might doubt this, but they are making in London solid drawn steel pipes. The price, of course, was considerable; but if you want a good article you must pay for it. Some 30 years ago he used a considerable quantity of wrought-iron pipes with wrought-iron flanges, and found that a wrought-iron flange bored out conical a little and riveted on the pipe made a perfect joint, and he had no trouble at all with this joint.

Mr. TREMLETT CARTER said he did not agree that electric welding was *merely* a process of soldering or a process of the flux of metal. The electric current seems to carry the melted metal of one part of the weld into the metal on the other surface, so that the two are interlapped and not merely stuck together. This is very evident when we try to weld copper or brass to steel, a thing which it would be very difficult to do by the ordinary process. He said he would like to call attention to another point. He thought the author ought to have given some particulars of the relative cost of the different processes. In America, where the Thomson-Houston process is very largely used for all kinds of metal work, welding and forging work, the cost has always worked out very much cheaper than the ordinary mechanical and thermal processes. In this country he was not sure whether the cost is always cheaper. He knew it had worked out so in one or two cases in this country. He should like to know the cost of electric welding as compared with the cost of the furnace processes, and the saving of time and labour effected. The saving in time and labour which was effected by using the electric process was one of its most distinctive features.

The PRESIDENT said we must all admit that the Paper was a very able one, and the question of having a reliable steam pipe was a very important one, and perhaps Mr. McCarthy, in reply to the various questions, would say something about Mr. Howell's remarks.

Mr. McCARTHY, in his reply, said he thanked Mr. Schonheyder for calling attention to a little error which had been made in the drawings, and if he would look at the samples he would see that there is a corner inside. Of course, the corners were nothing like so round as shown on the drawings. With regard to what Mr. Howell said about electric welding not being welding at all, but electric soldering, that had been stated a good many times. Call it fusing if you like. But he was prepared to show that it is a perfectly sound process. It was very interesting to hear what Mr. Howell said about the tube, but he did not think it had any bearing on the Paper at all, unless it was to show that the welded part of the tube was stronger than the other part. With regard to corrosion, it will affect pipes, whether in iron or steel or anything else, but taking the ordinary run of steel, he should say, from his experience, that there is no corrosion. With regard to the 12in. solid drawn pipes, he said he should like to know something about the cost of these. He has to thank Mr. Robinson for the very interesting particulars he had given with regard to the 4in. lapwelded tubes. Mr. Robinson had, no doubt, very good reason for recommending that the joints should be narrower, and he would mention that to Mr. Bailey when he saw him. With regard to screwed joints, he was not going to preach against them, because there were a lot of them on the table, but his idea in bringing this Paper forward in connection with moderately high steam pressures, was to bring forward what he believed to be the very best, and that was electric welded tubes. With regard to Mr. Carter's inquiry about the comparative cost, he was sorry that he was not in a position to give it. It was rather a delicate matter.

## TESTS OF A 10-CAR ELECTRIC RAILROAD.*

BY JOHN F. VAUGHAN.

The electric street railway from which these figures were taken consists in a newly built line of single track, ten miles long, running north and south across an open and somewhat hilly country, and an eleven-mile loop, several years old, leaving the main line near the south end and meeting it again about two miles from the north end. A short spin leaves the line near the south end.

The power for this road is derived from a station about three-quarters of a mile south of the south end, occasioning about 25 volts drop before the track is reached, although the station regulation is good. The data may be tabulated as follows:

| | | |
|---|---|---|
| Miles of track | | 22½ |
| Number of cars in service | | 10 |
| Car mileage per day | | 1,750 |
| Average speed (including stops) | miles | 9½ |
| Average current per car (during run) | amperes | 20 |
| Watt-hours per car mile (at station) | | 1.500 |
| Watt-hours per car mile (by wattmeter on car) | | 1,090 |
| Station potential | volts | 560 |
| Average potential on line | volts | 448 |
| Maximum drop on line | per cent. | 49 |
| Average feeder losses (calculated) | „ | 14 |
| Average ground losses (measured) | „ | 15 |
| Line efficiency (at present) | „ | 71 |
| Line efficiency (with good bonding) should be | „ | 82 |
| Maximum observed station load (clear cold weather) | amperes | 450 |

The bonding on the old line is destroyed in many places, showing over 50 per cent. of the total line resistance in places. The line leakage varied from 2 to 8 amperes, according to the weather. The heaters added, on an average, 8 amperes per car.

A striking example of the effect of the position of the station on the economy of distribution is seen by comparing the above figures with those obtained on the assumption that half the power be taken, as is proposed, from a lighting station between the proper centre of distribution and the north end of the line. With the two stations and the same feeder system:

| | | |
|---|---|---|
| The maximum drop on line | 22 volts = 3 per cent. | |
| Average potential on line | volts | 546 |
| Average feeder losses | per cent. | 3·1 |
| Probable line efficiency | per cent. | 96 |

## ON THE INFLUENCE OF LIGHT UPON THE CHARACTER OF THE INFLUENCE MACHINE DISCHARGE.†

BY J. ELSTER AND H. GEITEL.

Some years ago we described in these *Annals*‡ the arrangement of a photo-electric experiment in which the brushes and sparks of a Holtz machine passing between a sphere as positive and a plate as negative electrodes were made to disappear by the illumination of the cathode by light of short wave length. The arrangement is very simple. A hollow plate of zinc is placed upon the negative pole rod of the machine, its front surface being amalgamated by rubbing a mercury drop on it with a piece of linen dipped in sulphuric acid, then rinsed with water and dried with tissue paper. If now the knob of the other pole rod is withdrawn until strong zigzag sparks pass, or till, on removing the condensers, a brush streams against the zinc plate with a crackling noise, and a piece of magnesium wire is lighted in the neighbourhood, the stream is extinguished as soon as bright light impinges upon the negative pole surface, reappearing as soon as the light vanishes. The experiment, striking enough owing to the sudden silence observed, appears even more remarkable if we consider that in this case the illumination of the cathode effects the reverse of what might be expected after other experiments. Instead of a facilitation of the discharge, we have, in fact, an apparent impediment to it.

As we showed on that occasion, this influence of light is made even more conspicuous by introducing parallel to the spark gap to be illuminated another gap between brass knobs, adjusted so that in the dark the former is just preferred by the discharge. Under the influence of the magnesium light upon the zinc cathode the discharge then leaves the former path and passes by the latter. If we are also to apply the term "resistance of a gas stratum," to a spark discharge, this phenomenon may be shortly expressed by saying that the illumination of the cathode of amalgamated zinc increases the resistance of the spark gap.

The paradoxical result thus brought out led us to resume the investigation of this phenomenon. The following is a report upon our results.

The first supposition suggested by a comparison with other photo-electric processes is that, under the influence of light, the visible and

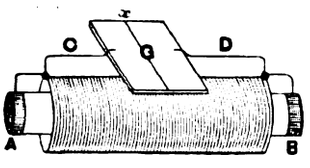
Digitized by Google

audible discharge is replaced by a silent one. The absence of any noise of streaming indicates that this form of discharge either takes place in a continuous manner, or that the alternations owing to high frequency or small amplitude no longer give rise to audible notes.

In order, first of all, to assist the ear to perceive the more pronounced discontinuities, we introduced into the circuit of the machine a telephone of the kind used by E. Wiedemann and Ebert for similar experiments. As was to be expected, the telephone was silent during illumination, and only after its cessation did the strong note accompanying the restored brush discharge set in. But still the discharge might have been discontinuous, if its frequency exceeded the limits of audibility or the resonance capacity of the telephone diaphragm.

To discover discontinuities of current of very small period, we employed the arrangement shown in the figure. An ebonite tube about 6cm. long is provided at both ends with metal tips A and B, and may be slipped with friction along a pole rod of the machine. An insulated copper wire 0·2mm. thick is wound to the extent of several hundred turns upon the tube in several layers separated by oiled silk, and the ends of the coil are attached to A and B. From these points two wires, C and D, lead to a small silvered glass strip G, the metallic coating of which is divided into two separate portions by the diamond cut $x$, as in Righi's resonators. The contact between the silver and the wires C and D is made secure by a small piece of gold leaf. If, now, the tube is mounted at A upon the pole-rod in such a manner that it only projects slightly into the interior, and the knob is mounted upon B by means of a suitable cylindrical piece of metal, every continuous discharge will take place through the wire coil, and the gap in the silver coating remains dark. But as soon as discontinuities or current surgings take place, the self-induction of the coil increases to such an extent that sparks appear at $x$.

After the little apparatus is arranged on the positive-pole rod, the zinc cathode is illuminated with magnesium light, and the machine is worked. As long as the light lasts, no sparks appear at $x$; but they appear at once, together with the sparks and brushes at the anode knob, as soon as the illumination is interrupted. The



gap $x$ is widened by corrosion to such an extent that the sensitiveness of the vibration indicator is much diminished. It is, therefore, necessary to insert a freshly-prepared Righi plate before each experiment.

The experimental result would, therefore, not be in the way of the supposition that under the influence of light the discharge of the machine passes into a continuous one. We may, at all events, conclude that the duration or the amplitude of the alternations are so small that they escape observation, even by the means specified. But are we to suppose that this new form of discharge consists solely in the photo-electric transference of negative electricity from the zinc cathode to the anode? This supposition appears questionable if we consider how small are the quantities of electricity transferred in air under atmospheric pressure in this manner. It may therefore be expected that the photo-electric dissipation taking place at the cathode also changes the form of the discharge at the anode, so that a practically continuous discharge takes the place of the sparks and brushes. Such a discharge can among known types only be represented by the glow discharge.

Since the magnesium light must only impinge upon the cathode surface, a possible glow process at the anode might perhaps be directly observed with suitable screens against the brilliant light. And in fact, on screening the eye and observing the anode sphere, also in the shadow, against a black background, it is seen that as soon as the zinc cathode is illuminated the brushes and sparks are replaced by a violet glow. The glow is the stronger the smaller the anode knob. Sometimes it remains for some time after illumination has ceased.

The experiment is facilitated by employing, instead of the magnesium, a flame of carbon bisulphide blown with oxygen. It is known that this is very rich in short-wave rays, and it does not blind the eye. It is, therefore, possible to observe conveniently the change in the form of discharge when the rays are allowed to reach the zinc surface; but the flame must be used with good ventilation arrangements, otherwise the sulphurous acid formed will soon stop the activity of the machine.

It is further remarkable that the change in the character of the discharge only occurs when the anode is actually hit by the electrified gaseous particles streaming from the cathode. If during illumination a perforated glass plate or a sheet of paraffined paper provided with a small hole is introduced between the anode and the cathode, brushes and sparks are at once formed at the anode. But a wire net put to earth and introduced between anode and cathode does not interfere with the photo-electric glow light. It must therefore be assumed that the electrified gas particles proceeding from the cathode go through the meshes of the net without quite parting with their charges. This result is quite in accordance with older experiments of W. Giese and later ones of Lord Kelvin. About the experimental arrangement we must remark that the wire net must be mounted in a metallic ring without any external projections from which brushes might issue to the neighbouring terminals of the machine.

An analogy is easily suggested with the process employed by Holtz* in order to produce and maintain a glow discharge. According to this investigator, the glow between the anode sphere and the cathode surface may be brought about by covering the latter with a layer of silk or several layers of tissue paper. This covering, we may suppose, has the effect of starting the discharge at the electrode at many points simultaneously, and thus distributing it over a large surface; but the very same must take place when the zinc cathode is illuminated by ultra-violet light.

The increase in the resistance of the air-space cannot be deemed surprising after the change in the character of discharge caused by the light is made plain. It is, indeed, not to be expected that under similar circumstances the various kinds of discharges transfer equal quantities of electricity. But in order to leave no further doubt on the question we made two further experiments apart from the introduction of a spark gap in parallel. We introduced an insulated Lane unit jar between the machine and the amalgamated zinc plate, while the positive terminal knob was placed opposite the latter at the distance of several centimetres. When the machine was worked and the condensers removed, a brush discharg eappeared at the gap, which disappeared in the light. At the same time, the machine being worked at a uniform rate, the discharge of the unit jar in equal times could be counted in the light and in darkness. It was observed that they took place somewhat more slowly during the illumination of the cathode, *i.e.*, that in the light during glow discharge, less electricity passed through the air-space, than in darkness through the brush discharge. From this it further follows, that in the light the difference of potential of the electrodes must increase. We showed this to be the case directly by means of a small cork pendulum mounted upon the electrodes with the aid of a rod ending in a sphere. During illumination of the cathode this gave a slight increase of potential, accompanied by a disappearance of the brush, more pronounced at the negative than at the positive pole.

Thus the glow of the anode produced by light gives less transference of electricity than the brush discharge in the dark. The question occurs at once whether, as indicated above, this only implies a difference between the two forms of discharge independent of light. The decision is made difficult by the circumstance that, without charging the electrodes or using light, the forms of discharge cannot be transformed the one into the other. But we may take it as probable that the question must be answered in the affirmative. For if the anode is a sharp point, which results in a glow discharge occurring in the dark, no difference in the resistance of the air gap is brought about by illumination. From this we conclude than an increase of resistance does not take place independent of the form of discharge. We had already in our previous communication mentioned that an existing glow discharge is not affected by light.

The chief results of the experiments described may be summarised as follows:—

The brushes and sparks of a Holtz machine passing between a cathode plate of amalgamated zinc and an anode sphere of any metal are replaced by a glow discharge when the cathode is illuminated by short-wave light. This glow discharge, during illumination, transfers a smaller quantity of electricity than do the brushes and sparks in the dark.

## AN INTERESTING ELECTRIC LIGHT PLANT IN COLORADO.*

The electric lighting plant of the Citizen's Electric Light Company at Leadville, in Colorado (10,000ft. above the sea level), is thoroughly representative of the latest modern practice in electric lighting. It is one of the first in America in which the principle of direct connection has been exclusively adopted, and one of the first also operating a very extensive public arc lighting system from incandescent circuits.

*Boilers and Engines.*—The station occupies a fireproof brick building with iron trussed roof. The boilers are three in number, 60 by 16ft., horizontal tubulars of 85 H.P., and are designed for a working pressure of 140lb. Space is left in the boiler room for an additional battery of three boilers. The smokestack is of steel, 4ft. 8in. in diameter and 90ft. high, set up on four iron columns. Two sets of duplex pumps, each pump of sufficient capacity to operate six boilers, and one feed water heater complete in boiler-room equipment. The three 85 H.P. Lake Erie engines are vertical cross-compound, with cylinders 7½in. by 13in. by 14in. Directly connected to each of the engine is a 50-kilowatt General Electric generator running at 275 revolutions per minute. The third engine has two 25-kilowatt generators of similar type, one on each end of the shaft, running at 300 revolutions. These generators are compound-wound 125-volt multipolar machines, with ironclad armature. During the first two months of the operation of the plant the overload on these dynamos daily ran up to from 25 to 40 per cent. without appreciably heating, while since December, 1895, according to the manager of the station, there has not been a night that all the dynamos have not carried an overload of from 10 to 20 per cent. without experiencing any difficulty.

*Switchboard.*—The switchboard is of the panel type, 13ft. long by 5ft. high. It is placed well away from the wall to give free access to the back. The conductors are brought to it under the floor and the switches and circuits are so arranged that any dynamo may be operated in conjunction with any other one or more, and on either side of the three-wire system. Two sets of feeders run from the board, and in the event of breakdown on one set the other may be called into requisition.

*Distribution.*—The plant is operated on the three-wire system, current being supplied to both arc and incandescent lights and motors. One engine, with the two 25 kilowatt dynamos, is designed to carry the night load from 2 to 5 a.m., the others being cut in as the demand for current requires. By having the generating units thus properly proportioned to the load and capable of being started and stopped at will, great economy of operation is gained, which would not be obtainable by the employment of one or two larger engines. Actual tests on the units installed at this plant showed over 82 per cent., delivered at the dynamo terminals.

The district covered by this system is a little over a mile square, and the lamps at present connected amount to an equivalent of 4,000 of 18 c.p. There are about 120 arc lamps of the new Thomson type, which have given excellent satisfaction. The circuits throughout the city are divided into sections, each of which is protected by proper safety devices, so that any trouble occurring on a section will affect that section only.

The main supply circuit consists of an endless circuit, making a complete enclosure. From this circuit are run the branch circuits supplying consumers east and west. This main circuit is fed at four symmetrical points by the two sets of feeders previously mentioned. The mains consist of three No. 0000 wires. The branches vary in size from No. 4 to No. 0000 wires, with a No. 000 for the neutral. The other feeder consists of five No. 0000 wires.

Since the first month of the operation of this plant the station has been running above its capacity, and business has been turned away. The installation of the fourth dynamo relieved the station but temporarily. The Company started by supplying current at a flat rate, intending gradually to introduce meters. The majority of consumers now have meters, and the load is gradually falling off, although the income is about the same; this shows the advantages of operating on the meter basis.

---

**A Telegraphic Girdle Round the Earth.**—A telegraphic message was despatched from the Electrical Exhibition now being held at New York, and, after making a double circuit of the globe, it returned to its starting-place, the time occupied being 50 minutes. President Chandler, of the Postal Telegraph Department, sent off the message, and Mr. Edison, sitting at the same table, received it.

* Abstract from the *Electrical Engineer* of New York.

## LONDON COUNTY COUNCIL.

At Tuesday's meeting the report of the Highways Committee containing the proposals of the Tramway Syndicate to lease the whole of the tramways from the Council and substitute electric traction, and the further proposals of the North Metropolitan Tramway Company to sell their undertaking to and subsequently lease them from the Council, came up for discussion.

Earl RUSSELL (in the absence of the Chairman of the Committee) formally moved the adoption of the report. He said he did so on the understanding that a sort of undertaking had been given that the merits of the question should not be discussed that day. An amendment had been moved to the recommendation of the Committee regarding the proposals of the Tramway Syndicate, and the Highways Committee thought it desirable that the discussion should take place on that as apart from the merits of the proposal of the North Metropolitan Tramway Company.

Mr. HOARE (Chairman of the Finance Committee), moved as an amendment "That the Syndicate's proposal be referred to the Finance Committee with instructions to consider and report as to their financial bearing." He said if the amendment was agreed to the Committee would confine themselves strictly to the bearing of the scheme on the financial position of the Council.

Ultimately, however, a motion to adjourn the discussion was agreed to.

The Bridges Committee brought up their proposal to construct a tunnel under the Thames from Millwall to Greenwich, referred to in our last issue, but the discussion of the subject was postponed.

The Works Committee recommended that the rate of pay for electric wiremen be increased from 8d to 9d. to 8½d. to 9½d. per hour, and this was agreed to.

The Chairman of the Highways Committee was asked by Mr. EMDEN when a report would be submitted in reference to the Council constructing subways; and by Mr. THOMPSON if there was anything to report with reference to the fire which took place in the subway at Northumberland-avenue the previous day.

EARL RUSSELL, in reply, said that nothing had been done with regard to subways at present. With respect to the fire in Northumberland-avenue, he was informed that it arose owing to some accident to the two electric wires in the Council subway. The wires became fused.

The consent of the Council was given to the making, by the Post Office, of a 1½in. pipe connection with the telegraph wires in Northumberland-avenue subway.

---

## AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May 8, 1896.*

**The National Electrical Exposition.**—At eight o'clock on the evening of Monday, May 4th, the National Electrical Exposition was opened in this city amid great enthusiasm. Governor Morton, of New York State, touched a golden key which turned on the current and set all the machinery in motion, at the same time turning on a blaze of light from thousands of lamps scattered throughout the hall. He stood in a framework of vacuum tubes, which also became illuminated at the moment he touched the key. The vacuum tubes were those of Mr. Macfarlan-Moore used in his system of "etheric" lighting, which has already been fully described in the electrical journals. Current from Niagara supplied the power for the illumination of miniature lamps used on the model of the Niagara Falls power plant. There were 8,000 people present during the opening evening, and since that time the Exposition has been very largely attended day and night. As has already been stated, the exhibition will continue through the month of May. The exhibits are very complete and well arranged, and everything in the electrical line is shown to the best advantage. The various historical exhibits attract much attention, and the working exhibits afford an excellent opportunity for the study of the different machines.

**The Nineteenth Convention of the National Electric Light Association.**—This Association met in the Exposition Building on May 5th, and the Convention continued for three days, adjourning on Thursday evening. It was a very successful meeting and was largely attended by the representatives of central stations throughout the country. While some excellent Papers were read, the standard was perhaps a little below the average. One of the most interesting Papers read was that on "The Commercial Value of Acetylene Gas," by Mr. L. A. Ferguson. Mr. Ferguson gave some figures on the cost of production of calcium carbide from which acetylene gas is produced. He also showed the cost per kilowatt hour, and that it would be

Digitized by Google

cheaper for central stations to utilize their energy in the daytime at lower rates than to use it for the production of calcium carbide. He stated the central station men need have no fear of acetylene gas, as under the most favourable conditions the cost of production of the gas is so much higher than that of electricity that there was no danger of acetylene encroaching on the electric light field or affecting the dividends of central stations. Mr. John F. Kelly read a Paper entitled, "The Evolution of the Inductor Alternator," and Mr. W. L. R. Emmet read one giving the results accomplished in distribution of light and power by alternating currents. "Steam Boilers, their Equipment and Management," was the title of an excellent Paper by Mr. Albert A. Cary. Other Papers of equal importance were read and well received. The social features of the convention were many. On the evening of May 5, Mr. Max Osterburg gave a lecture on "The Röntgen Ray," and on the next evening Mr. D. Macfarlan-Moore gave one on the subject of "The Light of the Future," which title he applies to his system of vacuum lighting. On Thursday night a large party, by invitation, visited the works of the Crocker-Wheeler Electric Company, at Ampere, N.J. A special train was chartered, and the crowd was so large that ten cars were required to carry the visitors. The works were thoroughly inspected.

**Honour to a Canadian.**—In connection with the Electric Light Association Convention it will be interesting to English people to know that a Canadian was elected as President for the ensuing year. This gentleman is Mr. Frederic Nicholls, who is closely indentified with electrical interests in Toronto, Canada.

## CORRESPONDENCE.

### ALTERNATING ARCS AND WAVE-FORMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With great interest I have read your editorial in the issue of May 1, 1896, on Mr. Frith's Paper on "Alternating Arcs." It seems to me, however, that the historical sketch given by you therein is rather incomplete.

In 1890, in a Paper read before the American Institute of Electrical Engineers by Messrs. Tobey and Walbridge, and published in the *Transactions* of 1890, p. 367, it was shown that the Stanley arc machine, when feeding a non-inductive or an inductive circuit, *i.e.* series incandescent lamps or a solenoid, gives practically sine waves of current and of E.M.F. If, however, alternating arcs, from 1 to 40, were inserted into the circuit, the E.M.F. wave changed to the most exaggerated form of a flat-topped wave—that is, a sharp double peak with deep hollow between (*see* illustrations *Transactions* American Institute of Electrical Engineers, and *Electrotechnische Zeitschrift*, 1892, p. 567), while the current remained practically a sine wave. A very satisfactory explanation of this phenomenon was given in the discussion by Prof. Pupin, in the periodically varying resistance of the arc, which is extremely high at or near the zero value of current, low near the maximum value.

The above mentioned machine was designed for series arc lighting by constant alternating current, thus of very high internal reaction, and therefore the current wave remained fairly sinusoidal while the E.M.F. wave changed. Inversely, with a machine of very low internal reaction, the E.M.F. wave would remain practically unchanged, and the current wave be distorted to single peakedness, that is, to the shape undesirable for arc lighting. An interesting result of this distortion was observed for the first time in the above-mentioned Paper, consisting in the appearance of a discrepancy between volt-amperes and watts, that is, of a power factor in the alternating arc without a displacement of phase, as discussed in *Electrotechnische Zeitschrift*, 1892, pp. 460 and 567.

Thus to conclude, it cannot be said that the alternating arc modifies the wave shape so as to be the best suitable, but rather that it introduces a discrepancy between the current wave and E.M.F. wave, resembling a very high apparent resistance of the arc at or near the zero value of current, and a low apparent resistance during high values of current, and thereby tending to distort the E.M.F. wave towards double peakedness and flat top, or the current wave towards single peakedness and flat zero, the former distortion being predominant in generator circuits of high internal reaction, the latter in circuits of low internal reaction.—Yours, &c.,

CHARLES PROTEUS STEINMETZ.

### THEORY OF THE SECONDARY BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have been greatly interested by your Editorial Notes this week on the theory of secondary batteries, and with reference to them I should like to point out that you are not quite correct in the statements made in your third paragraph as to there being no "hydrate" theory in existence before 1892.

If you will refer to *The Electrician* for April 1, 1887, you will see that the "hydrate" theory is there described in a letter written with reference to Mr. Fitzgerald's tests of his lithanode plates. Since that date I have made a vast number of experiments on all types of lead batteries, but have never arrived at any result which would cause me to alter the views then expressed.—Yours, &c., H. W. BUTLER.

4, Great Winchester-street, London, May 19, 1896.

### PHOTOGRAPHY OF LIGHTNING FLASHES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I enclose a photograph of a flash of lightning which I have just received from a friend in Buenos Ayres, who writes under date March 25, 1896, "I thought you might be interested in one of the enclosed photos, which I was lucky enough to get, of a splendid flash of lightning not long ago;

it might be of use to some scientific man." He, however, does not say whether the negative was taken with a hand camera or not, but I judge this was the case.

Can it be that each of these fine lines represents a distinct oscillation of the discharge? And is the ribbon appearance of three of them due to halation of the plate? It will be noticed that the apparent spiral striations of the broader bands are in alternate directions in each. Perhaps some of your readers can throw some light upon this.—Yours, &c.,

Bexley, Kent, W. G. LITTLE.
May 7, 1896.

### FUNDAMENTAL MAGNETIC UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have just seen a copy of your paper for April 24th, in which is printed my article on "Fundamental Magnetic Units."

I do not think it is hard to obtain a conception of the axis of a magnet without the use of "magnetic fluids." The direction of a uniform field is that which a *thin* magnet needle magnetised in the direction of its length assumes when freely suspended in the field. The axis of a magnet is that direction in the magnet which coincided with the direction of the field when it is freely suspended. Perhaps this looks a little like reasoning in a circle, but the conception of a thin magnet

Digitized by Google

does not seem very hard to obtain; in the earth's field such a needle points north. I believe the terms "broadside on" and "end on" are used quite commonly to indicate the orientation of the deflecting magnet in the second and first position of Gauss. In any case, the meaning to be attached to these terms can be seen in the definition of unit magnetic moment, which immediately follows them in the article.

I presume that the most scientific way of attacking magnetism in accordance with modern views would be to study the polarisation of the whole of space, both within and outside the magnet. I fancy, however, that it would be hard to frame a definition of the unit of polarisation that would bring the new system of units into numerical harmony with those now in use. This is certainly one advantage of the unit magnetic moment.—Yours, &c., H. N. ALLEN.

Nebraska, Lincoln, U.S.A., May 8, 1896.

## ELECTRIC MINING PLANT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I note in your issue of March 27th that the *Financial News* of 24th of that month is quoted as having stated, on the authority of the directors of Moodie's Fortuna Gold Mining Company, that electric power has not proved suitable for running their battery. As engineer in charge of Moodie's transmission plant, I beg to inform you that the facts of the case have been by no means correctly represented. The consulting engineer to the Fortuna Company has expressed a most favourable opinion as to the suitability of electric motors for battery running, and has, in fact, as manager of a neighbouring mine, been able to declare a dividend by the use of power derived from the same source as that which supplied the Fortuna Company.—Yours, &c.,

Moodie's, Barberton, S.A.R., April 24, 1896. H. J. S. HEATHER.

## ELECTRIC TRANSMISSION AT ROMAGNANO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Our attention has been drawn to an article in your current issue taken from *l'Elettricista* of a few months back, describing the electrical transmission of power for the Vonwiller paper mill in Romagnano.

We would remark that the word "alternations" is likely to be misunderstood. The frequency employed in this installation is our normal one of about 12 complete periods per second (∿).

Further, in the remarks on the motors you give 7 per cent. as the drop of speed from synchronism at a load of 10 per cent. more than normal, whereas this is the total drop, which has to be shared between the turbine regulators and the motors, which latter have a drop of not more than 3 per cent. at this load.

As these points are of some importance a correction would oblige.—Yours, &c., BROWN, BOVERI AND CIE.

[We regret the occurrence of the error mentioned by Messrs. Brown, Boveri and Cie. in the article referred to. Our correspondents are, however, in error in attributing the source of the article to "*l'Elettricista* of a few months back." The article was sent to us by a foreign contributor, and would, of course, have been acknowledged in our usual manner had we taken it from the columns of a contemporary. —ED. *E.*].

## HORSELESS STREET BILL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As one of the earliest workers in the horseless carriage movement, and as the only person who has had the practical experience of running a horseless vehicle upwards of 5,000 miles through the traffic of London streets, I should be glad of this opportunity of expressing, on behalf of all those interested in this immense industry which is now looming on us, our grateful acknowledgment to the Right Hon. H. Chaplin, the Government and Lord Harris for the great attention and care—having due regard to all the interests involved—that has been taken by them in removing the obstacles that have hitherto stood in the way of horseless vehicle traffic. I do not think that this momentous epoch in this great question should be allowed to pass without also some acknowledgment of the services rendered in connection with this matter by one who has represented the London Chamber of Commerce, and has also been specially able to speak on behalf of the electrical section of the horseless carriage interest which will have most to do with street and town traffic, as opposed to country road work. I refer to Major S. Flood Page.—Yours, &c., RADCLIFFE WARD.

# PARLIAMENTARY INTELLIGENCE.

On Tuesday and Wednesday the Kidderminster and Stourport Electric Tramway Bill was under the consideration of a House of Commons Committee. The Bill sought for powers to construct and work an electric tramway four miles long between Kidderminster and Stourport, at an estimated cost of between £30,000 and £40,000. The point in which the Bill differed from its predecessors was in the fact that it was the first electric tramway venture which sought to cross the line of a railway company by means of a level crossing, and upon these grounds, amongst others, the Bill was opposed by the Great Western Railway Company only. Mr. Pollock, Q.C., on behalf of the opposition, contended that the passage of an electric line over their system by means of a level crossing would seriously interfere with the working of the Great Western Company's system. Earth currents would greatly inconvenience the working of their telegraphic system, and would be accompanied even with danger to the travelling public. Mr. Lewis Coward, Q.C., opposed this contention, and argued that the passing of an electric tram by means of a level crossing would be attended with no more inconvenience or danger than would be the disarrangement caused by an ordinary thunderstorm. Mr. Coward, however, did not strongly press this point, but urged that the Railway Company should, under the provisions of their original Act, erect a bridge at the point in dispute. The Council after considerable deliberation decided that the preamble of the Bill was proved, but required the insertion of a clause arranging for the construction of a bridge over the Railway Company's line in place of the proposed level crossing, £750, or about a quarter of the cost at the option of the Board of Trade, to be borne by the Tramway Company, who will also be called upon to bear the cost of such additions or alterations in the metallic circuits of the Railway Company as the Board of Trade may consider necessary to prevent interference with the signals and apparatus of the Company.

# TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

**SPECIAL NOTICE.—The 1896 (fourteenth annual) edition o "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Hand book is 7s. 6d., post free 8s. 3d. abroad 9s. The book is greatly enlarged is quite up-to-date, and includes the new Board of Trade Regulations.**

## NEW BOOKS AND EDITIONS.

*The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. The NEW EDITION is NOW READY. Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d. Will be ready first week in June.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

Digitized by Google

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

'THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition now ready. Price 2s., post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from Notes made by Mr. Parshall in his capacity as chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables. 30s., post free.

---

TENDERS INVITED.—The Corporation of Leeds require tenders for an electrical installation sufficient for working by the overhead system on a double track of tramway seven miles in length. The work is divided into seven contracts, details of which will be found in our advertisement columns. Tenders have to be sent in to the Town Clerk, Town Hall, Leeds, not later than June 20th, and particulars, plans, &c., can be obtained from the City Engineer, Municipal Buildings, Leeds, or from Dr. John Hopkinson, F.R.S., 5, Victoria-street, Westminster, London, S.W.

——— The Hammersmith Vestry invite tenders for the erection of (*a*) an engine and boiler house, offices, &c., and (*b*) a chimney shaft 140ft. above footings. Tenders must be sent in to the surveyor (Mr. H. Mair), Vestry Offices, 57, Fulham Palace-road, Hammersmith, S.W., by the 27th inst.

——— The Aberdeen Town Council require tenders for supplying and erecting boilers, feed water heater, pumps and piping at the electricity works. Tenders to the Gas and Electricity Office, Town House, Aberdeen, by 10 a.m., 27th inst.

——— The Bradford Corporation invite tenders for the works required in the installation of electric lighting at Cliffe-road destructor works. Tenders must be sent to the Town Clerk, Town Hall, Bradford, by the 2nd prox.

——— The Oldham Corporation invite tenders for the supply of a jet condensing plant. Tenders to the Town Clerk, Oldham, by the 26th instant.

——— The Netherlands Minister of the Colonies invites applications for the supply of galvanised telegraph wire. Tenders to the Ministry, The Hague, by the 27th inst.

——— The State Small Arms Authorities at Spandau require tenders for the supply of 27,300 arc lamp carbons. Tenders to the Königliche Direktion der Gewehrfabrik, Spandau, Germany, by June 12th.

TENDERS ACCEPTED.—The Sunderland Town Council have accepted the tender of Messrs. John Hargreaves and Co., Rawtenstall, for the supply of an evaporative tubular surface condenser, with air and circulating pumps, for the electricity station.

——— The Lighting Committee of the Brighton Corporation have decided to recommend the acceptance of the tender of Messrs. Skeats and Co. for supplying 450 lanterns for incandescent electric lamps for £180.

——— The Portsea Guardians have accepted the tender of Mr. J. R. Penning, of Southsea, for wiring part of the workhouse for the electric light for £52. 10s. Tenders ranging from £44. 15s. to £113 were received.

——— It has been announced that the tender of the Brush Company has been accepted by the Hampstead Vestry for the supply of steam and exhaust pipes and feed water heater for their electricity supply station. We are asked to state that this is an error, the order having been placed with Wright's Patent Heater Condenser Company, of Westminster, London, the tender including the supply of Berryman heaters with special gear for cleansing, and the amount of the tender being £967.

——— The contract for the erection of the building for the Corporation Electricity Supply Works has been given to Messrs. Holme and King, of Liverpool, at £8,000, and the tender for erecting the chimney shaft has been let to Mr. Wm. Thickett, of Horbury, Wakefield, at £2,500.

SALE BY AUCTION.—Particulars will be found in our advertisement columns of the disposal by public auction by Messrs. Wheatley Kirk, Price and Goulty, on Tuesday, June 2nd next, of the entire contents of the late lighting station of the Reading Electric Supply Company (Limited), situated in Thorn-lane, Duke-street, Reading, Berks. The sale of this plant, &c., is taking place owing to the Company having completed their new central station. It will be seen that the sale includes two Babcock-Wilcox boilers, steam engines by Browett and Lindley, Alley and Maclellan, and Greenwood and Batley, Thomson-Houston dynamos, and a quantity of useful electric plant and apparatus, instruments, &c. Catalogues can be obtained from the auctioneers, or direct from the Reading Company.

BUSINESS FOR SALE.—From our advertisement columns it will be seen that private offers are invited for the business of electrical engineers and manufacturers lately carried on by Messrs. Morris Bros. (Limited), at Birmingham. Offers should be sent to the liquidator, Mr. E. J. Abbott, 9, Bennett's-hill, Birmingham.

APPOINTMENTS VACANT.—The Corporation of Lincoln, who intend to establish electricity supply works, invite applications for the position of electrical engineer. Salary £300 per annum. Applications must be sent in to Mr. H. K. Hebb, Clerk to the Urban Sanitary Authority and Deputy Town Clerk, by Saturday, June 6th. Some additional particulars are given in our advertisement columns.

——— The Municipal Technical Institute of the Borough of Salford invite applications for the post of (1) Chief Lecturer in Chemistry (salary £200); (2) Chief Lecturer in Dyeing (£150); (3) Art Master (£220); (4) an instrument maker (£2 per week). Some further information is given in our advertisement columns, and all particulars can be obtained of the secretary at the Institute, Peel Park, Salford.

——— There is a vacancy for an assistant electrical engineer at the Bolton Corporation electricity works. Applications to the Town Clerk, Town Hall, by Wednesday next, the 27th inst.

APPOINTMENT.—Mr. S. J. Ross has been appointed by the Hackney Vestry engineer and electrician at the public baths. The salary is £156 per annum.

DISSOLUTIONS OF PARTNERSHIP.—The partnership business of electricians hitherto carried on by Messrs. H. Patterson and G. J. Harford, under the style of Patterson and Harford, 49, Moorfields, Liverpool, has been dissolved. Debts by Mr. G. J. Patterson who continues the business under the old title.

——— Messrs. Edgar Isaac Everett and Charles William Brown, trading as electricians and engineers under the style of Everett and Brown, at 11, Albemarle-street, Clerkenwell, London, have dissolved partnership.

REMOVAL.—The London offices of the Chloride Electrical Storage Syndicate (Limited) have been removed from 16 to 39, Victoria-street, Westminster, S.W.

LIQUIDATIONS.—At a meeting of the proprietors of the Nalder and Harrison Construction Syndicate (Limited) on the 11th inst., it was decided to wind up the Syndicate voluntarily. This resolution was confirmed on the 27th ult., when Messrs. N. F. Nalder, J. A. McMullen, J. G. M. Hilton, and K. J. McMullen were appointed liquidators. As announced in our issue of the 8th inst., a new firm has been established to carry on the businesses of the Nalder and Harrison Construction Syndicate (Limited) and Messrs. Swinburne & Co. (Limited), under the style of Nalder and Hilton.

——— A meeting will be held at 137, West Regent-street, Glasgow, on June 17th, at noon, to receive an account of the winding up of Clark's Electric Launch Company (Limited).

THE GÜLCHER COMPANY'S AFFAIRS.—The creditors and contributories of this Company are notified that a meeting is to be held at 73, Lombard-street, London, at noon of the 26th inst. for the purpose of receiving from the voluntary liquidator an account of the Company's affairs in the winding up, and to consider an offer which has been made from the holders of Second Debentures. The report of the liquidator holds out no hope of any dividend for the holders of Ordinary or Preference shares or for the ordinary creditors, there being less than sufficient funds to discharge the ordinary costs of the liquidation.

WOODHOUSE AND RAWSON UNITED (LIMITED).—We have received a lengthy document from the directors of "The Manchester Electrical Works, Limited (successors to Woodhouse and Rawson)," which is in reality an invitation to the shareholders and creditors of the old firm to apply for shares in the new Company, described as having a capital of £50,000. Accompanying this document is a lengthy account of a meeting "of some of the principal shareholders of Woodhouse and Rawson United (Limited)," held in April last in response to a circular sent out by Lieut.-Col. N.

Digitized by Google

Willoughby Wallace, who was voted to the chair on the occasion. Col. Wallace described himself as one of the original shareholders in the Woodhouse and Rawson concern, and as a number of his friends had, on his instigation, taken shares in that Company, he felt desirous that some of the assets should, if possible, be saved. Inquiries showed him (Col. Wallace) that a contract had been made by Mr. F. L. Rawson with Mr. Leslie, the Receiver, to purchase the Manchester works, and also the supply business carried on at 88, Queen Victoria-street, London, together with the industrial patents and the goodwill of the business. These are described as being the two departments of the old Company which paid, and Col. Wallace considers that it will be worth the while of shareholders and creditors to retain and carry on this branch of the business themselves, together with the "financial patents" which have (according to Col. Wallace) also been purchased by Mr. Rawson, and have been handed over to a concern called the "Industrial Inventions Development Company (Limited)." It appears that Mr. Rawson is quite willing to hand over his purchase to the shareholders at the "actual cost," and Col. Wallace considers it will be well to take advantage of the offer. The Manchester works are described as being well organised and equipped, and, in addition to their own plant, possess the best tools from the London works. Col. Wallace further pointed out that it was extraordinary that nothing had been done (since the expiry of the Edison patent) with the Woodhouse and Rawson incandescent lamp, which he considered should now be taken in hand and pushed vigorously. One of the proposed new directors of the Manchester Company had negotiated for its manufacture abroad, and it was anticipated that a ready demand would be created in England for large quantities of the lamps at a low price. It was proposed to retain the services of Mr. Bertram Thomas, the manager at the Manchester works of Woodhouse and Rawson United (Limited), and a special clause was to be inserted in the Articles of Association of the new company binding the Directors "to do no outside financial business, and to confine the Company's operations to industrial business"! Mr. Thomas, who was present at the meeting, is stated to have read a lengthy report, which had been prepared some time previously, and in which figures were given showing that a new company, working with the old Company's tools and making similar goods, would have reasonable chances of success. He recommended the preparation of a new catalogue and the appointment for London of a good agent, acquainted with the customers of the old Company. The meeting, it is stated, carried a resolution that Col. Wallace and Messrs. D. E. Cardinall (a Director of a large Manchester brewery), and W. Pirrie (of Pirrie, Hope and Co., Newcastle), should be elected as the first Directors, at a remuneration of £100 for the first year. The final resolution of the meeting was:—"That a Company be formed, with £50,000 capital, to take over the Manchester works and the supply business of Woodhouse and Rawson United, and that the shareholders and creditors of Woodhouse and Rawson United have the right of applying *pro ratâ* for the first issue of £10,000 of such capital, with a minimum of £10."

EXPORTS OF ELECTRICAL APPARATUS AND MATERIAL.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from May 13th to May 19th, with the ports of destination:—

*Argentina*—Buenos Ayres, £100. *Australasia*—Adelaide, £15; King George's Sound, £799 (electric lighting apparatus); Launceston, £74; Melbourne, £171; Newcastle, £1,458 (electrical mining machinery); Sydney, £1,855 (including £1,050 telegraph cable). *Austria*—Trieste, £6. *Belgium*—Antwerp, £107. *Ceylon*—Colombo, £206. *Denmark*—Copenhagen, £58 (telegraph wire). *Holland*—Amsterdam, £50; Flushing, £43. *India*—Calcutta, £20. *Italy*—Spezia, £110. *Russia*—St. Petersburg, £1,342 (including £694 telegraph material). *South Africa*—Cape Town, £72; Delagoa Bay, £81; Durban, £63. *Sweden*—Gothenburg, £152 (telegraph material); Malmo, £5.

"LONDON."—Many of our readers will be interested in the "London Manual" for 1896-7, which is issued by the proprietors of *London*, 125, Fleet-street, E.C. Particulars are given of the constitution of the various local bodies which govern the metropolis, with their officials, and statistics regarding the committees and departments of these controlling bodies are included in the 260 pages of which the books consists. The published price is 1s.

SCOTLAND.—We last week referred to the Guide issued by Mr. MacBraine for the use of those intending to spend a holiday in Scotland. We have now to acknowledge the receipt of an extremely useful handbook, entitled "Mountain, Moor, and Loch," illustrated by pen and pencil on the route of the West Highland Railway. This is a second edition of the work, which contains 230 illustrations from original drawings made on the spot. Particulars of the principal show places on the West Highland Company's system are given, and the book should be in the hands of all who intend making Scotland their holiday resort for the coming season.

AMSTERDAM.—The British Consul at Amsterdam states that the Council of that town have come to an arrangement with the Telephone Company for the transfer of their undertaking on the expiry of their existing concession. The acquisition of the local tramways is also being considered, a vote in favour of purchase having already been passed by the Council, and just at present there appears to be a strong opinion in favour of the municipalisation of all public undertakings.

AYR.—The Town Council have received the sanction of the Secretary for Scotland for borrowing an additional sum of £5,000 for electric lighting purposes, bringing the total authorised up to £25,000.

BATH.—A special meeting of the Urban Sanitary Authority has been convened for to-day (Friday) to discuss the report of the Electric Lighting Committee recommending that application be made to the Local Government Board for permission to borrow £15,000 for the purchase of the City of Bath Electric Lighting and Engineering Company's undertaking, for providing capital for extensions of the mains and for defraying expenses incurred in obtaining a Provisional Order.

BURTON-ON-TRENT.—The infirmary is to be wired for the electric light. Current will be taken from the Corporation mains.

CALCUTTA.—A proposal for the establishment of electric light works in this city and for introducing electric traction on the tramways has been referred to the Indian Government. The question at issue is as to the employment of overhead wires.

CANTERBURY.—The City Council intend to erect a refuse destructor plant in conjunction with their electricity supply works, and have decided to borrow £20,000 for that purpose.

CHESTER.—The ceremony of laying the foundation stone of the electricity supply station was performed on Tuesday last by the Mayoress, Mrs. B. C. Roberts.

CHURCH LIGHTING.—St. Andrew's Presbyterian Church, Ealing, is now lighted electrically. The installation has proved successful and has given great satisfaction.

COLLIERY LIGHTING.—The electric light is to be employed in the workings and at the pitheads of the Hunter and Derwent Collieries at Medomsley, Durham.

EALING.—The electricity department of the District Council at present have orders on hand for an equivalent of 7,175 8 c.p. lamps, and 6,036 of these have been connected.

GLASGOW.—The Electric Lighting Sub-Committee have decided to send a deputation to Birmingham, Manchester and London for the purpose of inspecting and reporting on the systems of electric lighting employed in these cities.

GUILDFORD.—The Board of Trade have forwarded to the District Council a letter from the Guildford Electricity Supply Company, asking to be allowed to make an immediate start on the laying of the electric light mains. The Company state that 979 £5 shares have been allotted, and promises are in hand to take 100 more. The Council's consent will be given as soon as the Company submit a plan of the streets in which they propose to lay the mains.

ISLINGTON AND CITY ELECTRIC RAILWAY.—A House of Commons Select Committee has passed the preamble of the City and South London Railway Company's Bill for an extension of time until August, 1901, for constructing their line to Islington.

LEEDS.—The Yorkshire House-to-House Electricity Company have written to the Town Council offering to supply the necessary electrical energy for working the tramways.

LIVERPOOL.—Arrangements are being made for the completion of the purchase and transfer of the Liverpool Electric Supply Company's undertaking on July 1st.

LLANFAIRFECHAN (CARNARVON).—The new Convalescent Home, erected by Messrs. Heath, of Walsall, is to be lighted electrically.

MANCHESTER.—The accounts for the past year's working of the electricity department, which will shortly be submitted to the City Council, show a profit of over £11,000, against £5,500 for the previous year. It is stated that the demand for electric current has exceeded all anticipation, considerable extensions being in progress and further extensions are in contemplation. The capital expenditure to date is £175,000, and it was recently decided to borrow a further £100,000 for extensive additions to the station plant and mains. In December, 1893, there was an equivalent of 32,716 8 c.p. lamps connected; in December, 1894, and December, 1895, the figures were 60,298 and 93,200 respectively, while the number at the end of March last was over 103,000. The report states that fifty-one miles of single conductor have been laid, and in the course of the present summer mains will be laid in several additional streets. A reduction in the price of current (6d. per unit) is in contemplation.

Digitized by Google

MITCHELSTOWN (CORK).—At a recent meeting of ratepayers, called to discuss (amongst other things) the question of the lighting of the town, on the suggestion of Dean O'Regan a committee was formed for the purpose of collecting information and reporting. Mr. Webber, a local landlord and owner of water-power in the neighbourhood, has offered to light the town electrically by 36 incandescents for £66. 13s. 4d. per annum, the contract to be for a term of 21 years. This offer will probably be accepted.

OXFORD.—Under the presidency of Sir Henry C. Mance, Chairman of the Oxford Electric Company, a successful demonstration f the new photography was given in the Examination Schools on Tuesday by Mr. J. Hardie McLean and Mr. E. L. Birkbeck.

PORTSMOUTH.—The Town Council propose to apply to the Local Government Board for sanction to borrow £6,000 for electric light extension purposes. Mains are to be laid in St. Ronan's-road at an estimated cost of £200.

POWER TRANSMISSION PLANTS IN THE RAND.—The *African Review* states that the Koesterfontein Company propose to establish an electrical power plant for the purpose of supplying power to the various West Rand properties, at an estimated outlay of £20,000. The necessary works will be erected on Steenkoppies, and water power will be utilised in the generation of current, which will be supplied to any mine within 20 miles to the east or south-east, this radius including all mines on the Botha's or Randfontein reefs. The Company anticipate, in addition to supplying energy to their own mines, to be able to dispose of 1,000 H P. at £40 per horse-power per annum.

ROYAL INSTITUTION LECTURE.—On the occasion of Prof. Ewing's lecture on "Hysteresis" to-night, Messrs. Gabriel and Angenault will show examples of their duplex and other lamps.

RUSSIAN PATENT LAW.—The Russian Government have drawn up a Bill amending the patent laws of that country, which at present only awaits Imperial sanction. Under the new law the term of a patent is fixed at 12 years, and is subject to a tax of 20 roubles for the first year and 30, 40, 60, 80, 100, 150, 200, 300, 400, 500 and 600 roubles respectively for each succeeding year. Though an application fee of 30 roubles must in all cases be paid, a suspension of the tax for the first two years is granted to indigent patentees, but if the payment is not then made the patent can be annulled. Protests, which have to be filed at the courts, will only be considered within the first two years. Supplementary patents must be filed within one year of the issue of the original patent, and a fee of 30 roubles is payable on application, and an additional 20 roubles becomes due immediately the supplementary application is granted. A patent can be annulled (1) after it has been in force 12 years, (2) through irregularity in the payment of the annual tax, (3) through not being applied for, or not furnishing proof at the proper time, and (4) through the protest of a third party. Infringers of a patent are liable to a criminal prosecution as well as for damages.

SALFORD.—A Local Government Board inquiry was held at Salford on Wednesday into the application of the Town Council for sanction to borrow, amongst other sums, £5,000 for electric lighting purposes. It was stated that in September, 1893, the Council applied for sanction to borrow £50,000, but only a sum of £32,000 was authorised. In June, 1895, a second application was made for powers to borrow £18,000, but in this case only £7,770 was sanctioned. The present loan was required to meet expenditure in excess of estimates to the extent of £3,587, and for certain extensions to the plant. The application was unopposed.

STAFFORD.—It was stated at the last meeting of the Town Council that as a result of five months' working of the electricity works there was a small balance on the credit side.

ST. PANCRAS (LONDON).—The Vestry have decided to abolish all meter rents from July 1st next. The Electricity Committee have handed over £1,000 out of the profits on last year's working to the general account. Property adjoining the dust destructor station has been acquired for £1,450 in order to obviate a threatened action for injunction.

SOUTHPORT.—At the last meeting of the Town Council, Councillor Hulme said, in referring to the recent resignation of the borough electrical engineer (Mr. Arthur Ellis) and to the appointment of Mr. C. D. Tate to fill the vacant position, that they were sorry at losing Mr. Ellis, as he had proved himself to be a most efficient public servant. One or two members protested against the proposal to make Mr. Tate's salary £230 per annum, as Mr. Ellis only received £204; but the proposal was ultimately agreed to.

SUNDERLAND.—At the last meeting of the Town Council, Alderman Bruce announced that the receipts from the sale of current, meter rents, &c., for the past year amounted to £2,166, and the deficiency was only £701, which included an extra three months' interest. The actual output had been 95,446 units, and the average price realised 5·13d. per unit. Expenses and management came to £1,490, while interest and sinking fund absorbed £1,377. The results of the first year's working had exceeded their anticipations, and they had already received notifications, now that the reduction in the price of current had taken place, of considerable extensions. The Electric Lighting Committee had made arrangements for the extension of the station building and for putting down additional plant before September, so as to be in a position to meet the increased winter demand.

TARIFF CHANGES.—Under the new (1896) Argentine Customs Law electric light machinery and apparatus (except service fixtures) imported into the country are subject to an *ad valorem* duty of 5 per cent.——The German Customs authorities have decided that electrical, physical and scientific instruments, galvanic batteries, &c., will in future be charged with the duties applicable to the materials of which they are made.

WEST HAM.—The borough electrical engineer (Mr. Risch) has prepared a report on the electric lighting question, in which it is recommended that the electricity supply station be erected in conjunction with the pumping station, and that all the boilers be placed in one building. For private lighting Mr. Risch recommends the adoption of the high tension alternate-current transformer system, current to be supplied to consumers from sub-stations on the three-wire system at a pressure of 100 volts. For public lighting Mr. Risch proposes to run the arc lamps in series off a constant current machine. Incandescent lamps will be fixed to the arc lamp pillars to enable incandescent to be substituted for arc lighting after midnight. The borough engineer (Mr. Lewis Angell) and the electrical engineer have been empowered by the Council to settle details as to the working of the electric lighting and sewage plants.

# PATENT RECORD.

*A record of Applications for Patents and Patent Specifications Publishe is compiled for this journal by* MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

## APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

April 21, 1896.

8,380. B. F. MERRITT and J. M. JOY. London. Improvements in printing telegraph instruments.*

8,382. J. DEVONSHIRE. London. Improvements in automatic circuit-breakers for use in electric tramcars or other electrically-propelled vehicles. (W. B. Potter, United States.) *

8,397. H. EDMUNDS. London. Improvements in electrical cut-outs.

8,398. H. EDMUNDS. London. Improvements in or connected with electrical resistances.

8,399. H. EDMUNDS. London. Improvements in apparatus for completing interrupting, and controlling electrical circuits.

8,410. J. C. GRAHAM. London. Improvements in the electro-deposition of metals, particularly applicable to the deposition on wires.

April 22, 1896.

8,428. J. B. VERITY. Birmingham. A new or improved electric switch.

8,458. W. TURVEY. London. Improvements in electrical recording instruments

8,483. SIEMENS BROS. AND CO. (LIMITED) and W. DIESELHORST. London. An improvement in joints for electrical cables.*

8,507. J. HINKS AND SON (LIMITED) and F. R. BAKER. London. Improvements in chandeliers, gaseliers, electroliers and other hanging lamps.

8,512. G. W. DOLMAN. London. Improvements in or connected with drain pipes, water or electric conduits, and the like.

8,514. J. A. TIMMIS. London. Improvements in electric glow lamps.

April 23, 1896.

8,541. W. WOODHEAD. Halifax. Improvements in electric lamps for miners, and in the method of lighting said electric lamps.

8,569. E. TYER. London. Improvements in apparatus for making electrical contact by passage of a railway train.

April 24, 1896.

8,630. J. CHANDLER. Liverpool. Improvements in magnetic motors.

8,647. F. TUDSBURY. Sheffield. Improvements in induction electrical machines.

8,659. F. W. SCHNEIDER. London. Improvements in paste-carrying plates for electric accumulators.*

8,660. F. W. SCHNEIDER. London. Improvements in the construction of cells for electric accumulators.*

8,666. THE BATTERY AND MOTOR COMPANY (LIMITED) and H. T. BARNETT. London. Improvements in and connected with battery electrodes.

Digitized by Google

8,682. C. A. McEvoy. London. Improvements in hand grenades and in electrical firing apparatus applicable for firing the same.
8,684. F. L. Muirhead. London. Improvements relating to telephones.
8,695. W. Majert. London. Improvements in electrodes for accumulators.*

April 25, 1896.

8,743. H. A. Cutmore. London. Improvements in speaking-tube, telephone and the like receivers.

April 27, 1896.

8,802. C. Shore and C. Heap. Rochdale. Improvements in and relating to switchboards to be used for telephonic purposes.
8,810. J. Edmondson. Halifax. Improvements in dynamo electric machines.
8,815. G. Davis. London. Improvements in or connected with electric light switches.
8,819. J. W. Mitcherd. Merioneth. Railway pilotman's substitute apparatus, for working single line during failure of "tablet" or "electric" staff working.
8,846. H. Sandwith. London. Improved dynamo-electric machine.
8,853. H. Arzt. London. A new or improved construction or arrangement of generator of electricity.

April 28, 1896.

8,890. T. Meacock. Birmingham. Electricity and water supply for household and other purposes.
8,906. L. B. Atkinson and F. G. Treharne. Penarth. Improvements in the generation of electricity.
8,943. R. Williams. Chiswick. Improvements in the fixing of metal caps to incandescent electric lamp bulbs.
8,948. H. H. Lake. London. Improvements in electric signalling apparatus. (G. E. Painter, United States).*
8,964. O. Imray. London. Improvements in electrical furnaces. (D. Graham, Canada).
8,973. R. P. Strand, De B. Carritte and C. A. Stockton. London. Improvements in electrical organs.*

April 29, 1896.

8,999. A. M. Rosebrugh. Toronto. Duplex or multiplex telephony.
9,014. G. J. Baird. Glasgow. Improvements in electric temperature alarms.
9,030. W. W. Channon. London. An improved automatic electrical cut-out.
9,047. T. D. Farrall. London. Method of and apparatus for heating by electricity.
9,048. H. Tomlins and C. R. Gurr. London. Electrical fog signalling apparatus.
9,055. J. A. Timmis. London. Improvements in fire-proof cements and varnishes for electrical and other purposes.

May 1, 1896.

9,171. W. Fairweather. Glasgow. Improvements in underground conduits for electric railroad or street railway systems. (Munson, Roberts, Alston, Reid and Reid).*
9,233. H. A. Willey and S. Simpson. London. Improvements in prepayment-mechanism for gas, electricity, and other meters.
9,239. W. McMurtrie. London. Improvements in tools for stripping insulation from wires.*
9,257. C. Grahner. London. Improvements in and relating to electric arc Lamps.*
9,262. R. Pippette. London. Improvements in switch apparatus for use in distributing electricity for telephonic, telegraphic and other purposes.

May 2, 1896.

9,266. J. MacKenzie Urquhart and W. H. Dingle. London. Improvements in electric lighting fuses or cut-outs.
9,284. A. H. Walton. London. Improvements in automatic apparatus for switching gear of electrical transformers and other electrical circuits.
9,288. A. Marr. Manchester. Improvements in telephonic receivers.
9,289. W. E. Heys. Manchester. Improvements in and connected with the electro-deposition of copper. (E. Dumoulin, France).
9,332. A. Rinclake. London. Improvements in and connected with permanent electric ways.
9,362. W. B. Sayers. London. Improvements in dynamo electric machines.

May 4, 1896.

9,402. O. von Morstein. London. Improvement in electric gas lighting devices.*
9,447. A. G. Cooke. London. Improved reversible variable speed gear applicable for use in electrical regulation and other purposes*

May 5, 1896.

9,480. A. S. Krotz, W. P. Allen and O. S. Kelly. Manchester. Improvements in electrical contacting devices for subways or conduits.*
9,517. W. R. Sykes and F. T. Hollins. London. Improvements in electric locking and block signalling on railways.
9,528. H. H. Lake. London. Improvements in telegraphic relays and the like. (C. G. Burke, United States.)*
9,530. J. Devonshire. London. Improvements in sockets or holders for incandescent electric lamps. (H. C. Wirt, United States.)*
9,531. J. Devonshire. London. Improvements in dynamo-electric machines. (C. P. Steinmetz, United States.)*
9,534. J. Lavender. London. Improvements in electric switches for use with or without mechanical or electromagnetic brakes.
9,537. J. Lavender. London. Improvements in or relating to electro-mechanically propelled vehicles.
9,555. T. A. Clarke. Liverpool. Improvements in or connected with electric burglar and other alarms.
9,565. M. Schindler. London. Improvements in or connected with electric melting apparatus.

May 6, 1896.

9,619. S. P. Eastick and E. Sayer. London. Improvements in incandescent electric lamps.
9,637. A. Blahnik. London. Improvements in arc lamps.
9,650. E. Lanhoffer. London. Improvements in electro-motors and dynamos and in apparatus for use therewith.*

May 7, 1896.

9,667. W. Fox. Broughton. Electric arc lamps.
9,668. W. Fox. Broughton. Electric arc lamps and projectors.
9,681. H. L. P. Boot. Tunbridge Wells. An improved method of street lighting by glow lamps.
9,713. D. Foulis. Glasgow. A signal indicator for use on locomotives, and means for electrically operating the same.
9,758. F. Fanta. London. Improvements in floorcloths or carpets for the purpose of electrical distribution therein.

May 8, 1896.

9,806. H. Pieper, Fils. London. Improvements in apparatus or devices for starting and arresting electro-motors employed in driving wire-drawing or other similar machines.
9,817. E. Bach, H. S. Lewis and A. B. Saunders. London. Improved shade for use in connection with electric incandescent lamps and the like.*
9,820. M. Binswanger and F. G. Bell. London. Improvements in coupling boxes for electrical circuits.
9,832. J. E. Kingsbury. London. Improvements in telephone systems of exchange. (The Western Electric Company, United States.)
9,843. R. P. Wilson. London. Improvements relating to electric current meters.
9,853. E. S. Collicott. London. Improvements in and connected with electric belts and like appliances to be worn next the skin.*

May 9, 1896.

9,910. A. Schanschieff. London. Improvements in secondary batteries.
9,919. W. Friese-Greene. London. Improvements in and related to exhausted tubes for electrical and other purposes.
9,929. R. W. Lane. London. The self-returning electric bell indicator.

## SPECIFICATIONS PUBLISHED.

# COMPANIES' MEETINGS AND REPORTS.

## West India and Panama Telegraph Company (Limited.)

The thirty-eighth ordinary general meeting of the members of this Company was held at Winchester House, Old Broad-street, on Wednesday, Mr. C. W. Earle presiding.

The SECRETARY (Mr. R. T. Brown) read the notice calling the meeting and the minutes of the last meeting, the report of the Directors and statement of accounts being taken as read,

The CHAIRMAN said: Gentlemen, we who are engaged in carrying on the business of the West India and Panama Telegraph Company are always very thankful for small mercies, and it is with some satisfaction that we note that the long-continued decrease in the traffic receipts that we have had to report at a good many meetings has at last taken a turn, there having been an increase of £1,083 as compared with the December half of 1894. It is quite true that that little benefit is wiped away almost entirely by the loss of the French subsidy from Guadeloupe. However, that was a contingency we foresaw with certainty in respect to the French Government and her colonies. It was a loss which we had no means of escaping from. The traffic receipts of this Company, considering the extent of its cables—about 5,000 miles, serving 16 different colonies—are almost ridiculous, the gross amount being about £2,300 a fortnight. When I happen to look over the receipts, not of telegraph but of other companies, I am struck with the extraordinary disparity of the results. Take, for example, that very excellent company called the Sweetmeat Automatic Delivery Company. It has almost double our receipts from selling, on the penny-in-the-slot principle, butter-scotch, chocolate, and that sort of thing, at our railway stations; but here is a great and important enterprise, that does so much for the Government of the country and holds together a great section of our colonial empire, which does not derive so much from its business as a company of that modest nature. In the accounts there is very little to remark upon. Situated as we are, we are obliged to keep down our expenditure to the very lowest sum consistent with an effective service, so that there is very little variation in those items over which we have control. One point of advantage in the accounts is the decrease under abstract "C," dealing with the expenses attending repairs and renewals of cables. This half year, owing to our having to put in the system 30 knots of cable less than we did in the corresponding period of the previous year, there is a considerable diminution in expenditure on cable repairs. In fact we have only had to charge ourselves with £2,831, as against £5,576 in the corresponding half of last year. There has also been an advantage in our having brought home the "Grappler" to take out a new supply of cable for stock, because if we had not brought our own ship home, we should have had to charter a vessel to carry out the new stock of cable. We have charged the cable so carried out with a fair amount of the expenses of the "Grappler" during the voyage home and out. That has saved us a sum of about £2,000. If it had not been for that saving we should not have been able to pay the wretched dividend on the ordinary shares that we are now offering you. With regard to paragraph 5, which deals with the reduction from £600 to £400 in the St. Vincent subsidy, I am almost inclined to think that the last words of the first part of the paragraph are too mildly expressed, and had not the colony of St. Vincent been in the old days one of the most liberal to us of all the British possessions we should have been inclined to use stronger terms. If the question of depression in one's circumstances is to justify one's not paying for what one gets, I think that this Company especially ought to have a strong claim under that depression principle. But the reduction has been approved by the Secretary of State for the Colonies, and therefore we must bow to his decision. Mr. Chamberlain is a fair man and a good man of business, and he is not likely to do anything that he thinks unjust or inexpedient. I dare say most of you will have seen the answer of Mr. Chamberlain in the House of Commons when he was asked about the proposed cable between Bermuda and Jamaica. We have been in communication with the Colonial Office with regard to that cable, and I need not say that it would be very improper to make any statement now on that correspondence. When the time comes if anything is settled we shall place the result before you and ask your opinion upon such terms as may be proposed to us. The question of that cable is a very old one. In 1882 there was a Conference of the colonies held at Barbadoes, at which it was advocated that that cable should be laid, and very strong pressure was put on the Government to do so. It was rather hard on us, considering that we had laid this system under conditions imposed by the legislatures of the West Indian colonies as to route and tariff, to be told when it was thought that our rates were rather high that they were to have a cable subsidised by Her Majesty's Government to compete with us. I must therefore read what Mr. Fawcett, who was then Postmaster-General, had to say on the subject: "Undoubtedly the Company have had great difficulties to contend with, but Mr. Fawcett believes that the present Board are striving to put their property on a sound basis, and, notwithstanding the opinion expressed by the Conference, that the Company have failed to meet the requirements of the West Indian Colonies, he fears that there would be just cause for complaint against Her Majesty's Government if it were now to subsidise a rival company, especially as such a company would in all probability require not much less support in the shape of subsidies than the present Company lays claim to, and directs me to observe that he thinks that any company would have reasonable ground for objecting to supply the bulletin of news which the Company are called upon to furnish free of charge." Now, influenced I may say by these words, the Company went on its course and continued the duplication of its system, which has given permanent and constant security in communication with the West Indies, and I am quite certain that any colonial minister or statesman of the present day, if these words of a very eminent public servant, the late Mr. Fawcett, were brought to his notice, would think that it would be a very unjust thing to employ the money of the ratepayers of this country for such a purpose. I shall be very glad to answer any questions that may be now put. Meantime I shall in conclusion move—

*"That the Directors' report and accounts to December 31, 1895, submitted to this meeting, be and the same are hereby received and adopted, and that, as recommended by the Board, a dividend of 6s. per share on the First Preference Shares, 6s. per share on the Second Preference Shares, and 6d. per share on the Ordinary Shares (the last free of income tax) be and the same are hereby declared."*

Mr. WM. ANDREWS seconded the resolution, which was carried unanimously.

The CHAIRMAN then moved the re-election of Mr. Andrews, the retiring Director, to his seat at the Board.

Mr. HENRY HOLMES seconded the motion, which was carried unanimously.

Mr. ANDREWS having briefly expressed his acknowledgment,

Mr. JOHN NEWTON moved, and Mr. CUFF seconded, the reappointment of the auditors, Messrs. Deloitte, Dever, Griffiths and Co.

The motion having been agreed to,

Mr. CUFF moved, and Mr. NEWTON seconded, a vote of thanks to the Chairman and his colleagues on the Board, for which the former briefly returned thanks, and the proceedings ended.

# NEW COMPANIES, STATUTORY RETURNS, &c.

*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1896, pages *318-346, &c., &c.*

**R. H. ACQUISITION SYNDICATE (LIMITED).**—This Company was registered on May 14th, with a capital of £5,000, in £50 shares, to carry on, amongst other businesses, those of mechanical engineers, electricians, electric light manufacturers and suppliers, machinists, metallurgists, electro-platers, &c.

**W. A. BAKER AND CO. (LIMITED).**—This Company has been registered with a capital of £100,000, in 5,000 Preferred and 5,000 Ordinary shares of £10 each, to acquire the business of electric light engineers and contractors, general ironmongers, founders, &c., carried on under the style of W. A. Baker and Co., at Newport, Mon. The first Directors are W. A. Baker, M. Mordey, J. T. Hamilton, and J. E. Baker.

Digitized by Google

**CARBON (FOREIGN PATENTS) SYNDICATE (LIMITED).**—This Company was registered on May 14th, with a capital of £100,000, in £1 shares, to carry into effect certain agreements with Messrs. C. P. Shrewsbury, J. Cooper, F. L. Marshall and J. L. Dobell, and to carry on the business of manufacturers of and dealers in carbon plates, slabs, rings, crucibles, rollers, bars, rods and other articles for electrical, electrolytical and other purposes, and electrical and mechanical engineers, electricians, suppliers of electricity and manufacturers of and dealers in electrical apparatus of all kinds. The first subscribers, with one share each, are: Major A. D. Seton, J. Lindsay, F. L. Marshall, C. P. Shrewsbury, engineer, J. Cooper, S. Spill and J. L. Dobell, electrical engineer. The first Directors are: Major A. D. Seton, C. P. Shrewsbury, J. Cooper, F. L. Marshall, H. Dobbin and S. Spill.

**DIRECT ELECTRIC GENERATOR (FOREIGN PATENTS) SYNDICATE (LIMITED).**—This Company was registered on May 14th, with a nominal capital of £100,000, in £1 shares, to carry into effect certain agreements with Messrs. C. P. Shrewsbury, J. Cooper, F. L. Marshall and J. L. Dobell, to acquire, develop, and deal with any patents, licences, concessions, &c., and to carry on the business of electricians, generators and suppliers of electricity, mechanical engineers, and manufacturers of and dealers in all apparatus required for or capable of being used in connection with the generation, distribution, supply, accumulation and employment of electricity. The first subscribers, with one share each, are Major A. D. Seton, J. Lindsay, F. L. Marshall, C. P. Shrewsbury, engineer, J. Cooper, S. Spill and J. L. Dobell, electrical engineer. The first Directors are: Major A. D. Seton, C. P. Shrewsbury, J. Cooper, F. L. Marshall, H. Dobbin and S. Spill.

**GREAT HORSELESS CARRIAGE COMPANY (LIMITED).**—This Company was registered on May 14th, with a nominal capital of £750,000, in £10 shares, to acquire certain patents and patent rights, and to carry on the business of horseless carriage, cycle and motor manufacturers, repairers and dealers, electricians, mechanical engineers, machinists, wire drawers, metallurgists, electro-platers, &c.

**PRINTING TELEGRAPH RECORDER COMPANY (LIMITED).**—This Company was registered on May 15th, with a capital of £10,100, in 10,000 Ordinary, 100 Founders' shares of £1 each, to acquire, develop, and deal with any patents, inventions, concessions, &c., to carry on the business of manufacturers and repairers of and dealers in all telegraphic apparatus and particularly type-printing and other telegraph recorders and instruments, telegraph engineers, &c. The first subscribers are H. Moir, G Gray, engineer, W. G. Brookman, engineer, J. Girdwood and Hon. Henry J. Saunders, and H. M. Willis and A. Barrett. The first Directors are J. Moore, W. P. Forbes and (after allotment) W. S. Steljes.

---

**CORLETT ELECTRICAL ENGINEERING COMPANY (LIMITED).**—The annual return to May 14th has been filed. The nominal capital is £10,000, in £10 shares; 620 have been taken up, and 100 of these have been issued as fully paid. The full amount has been paid on the remaining 520 shares.

**HASTINGS AND ST. LEONARDS-ON-SEA ELECTRIC LIGHT COMPANY (LIMITED).**—The annual return to May 8th has been filed. The nominal capital is £50,000, in £10 shares, and 2,722 of these have been taken up. The full amount per share has been paid.

**NORWICH ELECTRICITY COMPANY (LIMITED).**—The annual return to April 29th has been filed. The nominal capital is £50,000, in £10 shares; 3,525 have been taken up, and the full amount has been called and paid.

**ORIENTAL TELEPHONE AND ELECTRIC COMPANY (LIMITED).**—The annual return to May 6th has been filed. Out of a nominal capital of £200,000, in £1 shares, 171,504 have been taken up, and 171,497 of these have been issued as fully paid. The full amount has been paid on the remaining seven shares.

**TELEPHONE COMPANY OF EGYPT (LIMITED).**—The annual return to May 5th has been filed. The capital is £100,000, in 16,000 Preference and 4,000 Deferred shares of £5 each: 12,071 of the former and all of the latter have been taken up, and 12,000 Preference and 4,000 Deferred have been issued as fully paid. The full amount has been paid on the remaining 71 Preference shares.

## CITY NOTES.

**MEMORANDA.**—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 31 1/16d. per oz. (May 21st). Consols (2¾ per cent.) 112 3/8—112½ for money, 112 7/16—112 9/16 for account; 2½ per cent. 106⅛—106⅜ (May 21st). Stock Exchange Settling Days: Consols, June 1st; Stocks and Shares Continuation Day, May 27th; Ticket Day, May 28th; Pay Day, May 29th; Mining Share Carry-over Day, May 26th.

**BIRMINGHAM CENTRAL TRAMWAYS COMPANY (LIMITED).**—Messrs. W. Mackenzie (President of the Toronto Railway Company) and J. Ross Managing Director of the Montreal Street Railways Company) have made an offer to purchase the undertaking of the Birmingham Central Tramways Company on the basis of a par value for the debentures and Preference shares, and a bonus of £1 on the Ordinary shares. The authorised capital of the Company is £300,000, of which £194,000 has been issued in fully-paid Ordinary of £5 each, and £100,000 in Five per Cent. £10 Preference shares; and, in addition, there are debentures for £152,400. The last dividend on the Ordinary shares (1894-5) was at the rate of 3 per cent. The Directors of the Company have issued a circular, in which they strongly recommend the shareholders to accept the offer, stating that, though the operations of the Company since the last meeting have been satisfactory, any future improvement in their position must be effected by the adoption of an improved system of mechanical traction on the routes at present worked by steam. As soon as the Corporation have expressed approval of the proposal, meetings of shareholders will be called for the purpose of considering and approving the agreement proposed to be entered into between the parties, and for passing the usual liquidation resolutions.

**BUSINESS CHANGES.**—Owing to the increased demand for their well-known patent water-tube steam boilers, the business of Messrs. Conrad, Knap and Co. has, we are informed, been converted into a private limited liability company, under the style of Conrad, Knap and Co. (Limited). No shares are offered to the public.

**CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).**—The traffic returns of this Company for the week ended May 17th were £864, against £905 in the corresponding week of 1895, a decrease of £41. The total receipts for the half-year amount to £18,800, against £18,720 for the corresponding period of 1895, an increase of £80.

**COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY (LIMITED).**—In reference to the recent issue of 10,000 Preference shares of this Company, we are informed by the Electric and General Investment Company that applications for over four times the amount offered were received.

**LIVERPOOL OVERHEAD RAILWAY COMPANY.**—The traffic receipts of this railway for the week ended 17th inst. amounted to £1,125. The amount for the corresponding week last year was £1,141; decrease, £16.

**LONDON ELECTRIC OMNIBUS COMPANY (LIMITED).**—This Company, which has been formed for the purpose of acquiring and working Mr. Radcliffe Ward's system of electric street traction, invites application for 170,000 £1 shares, payable 5s. on application, 5s. on allotment, and the balance in instalments of 2s. 6d. per share, at intervals of not less than one month. The authorised capital of the Company is £250,000 in £1 shares. The prospectus, which will be found in our advertisement columns, states that the entire purchase money except £20,000 will be taken in shares which will not participate in dividends until sufficient profits have been earned to pay in any one year a dividend of 7 per cent. It is claimed that the working capital allowed for is sufficient to provide for 125 omnibuses, running 70,000 miles per week. The Directors include Major S. Flood-Page (Director of the Edison and Swan United Electric Light Company), and Mr. Radcliffe Ward, who is also the Company's engineer. The manager and secretary (*pro tem.*) are Messrs. H. F. Lewis and A. Caillat, and the offices are at 36, Broad-street House, London, E.C. The list of applications closed yesterday (Thursday) for town, and will close this (Friday) morning for the country.

**NORWAY.**—6,000,000 kroner is to be devoted to the development of the telegraph and telephone systems of Norway, out of an issue of a new State loan of 25,000,000 kroner.

**READING ELECTRIC SUPPLY COMPANY (LIMITED).**—The annual general meeting of this Company was held last week at Reading. The Chairman (Mr. H. Collins) said the income for the past year amounted to £1,453. 10s. 7d., and the net profit to £22. 13s. 4d., and the Directors considered these figures to be satisfactory, seeing that the new supply station was only in operation for the last two months of the year. There was an increased demand for current, and they anticipated a greatly increased revenue in the forthcoming year. At the end of 1895 they had 83 customers, representing 6,094 8-c.p. lamps, and at present these figures were 115 and 6,647 respectively. The price of current has been reduced from 8d. per unit (with discounts) to 6d. net, and as the Directors are anxious to create a day load they have decided to fix the price of current for motive power, cooking and heating purposes at 3d. per unit.

**REUTER'S TELEGRAM COMPANY (LIMITED).**—The report of the Directors of this Company, to be presented at the shareholders' meeting on the 27th inst., states that the net profits for the year ended December 31st last amount to £11,340. 12s. 3d., including £1,718. 16s 5d. brought forward from the last account. The sum of £6,382. 5s. 1d. has been placed to reserve, which now amounts to £14,000. The Directors propose to pay a dividend of 4s. per share, equal to 2½ per cent., making, with the interim dividend of 2½ per cent. paid in October last, a total distribution of 5 per cent. for the year. This will absorb £4,781. 10s., and the balance of £176. 17s. 2d. has been carried forward. The Directors state that they have decided to retain the advertisement business.

**SUSSMANN ELECTRIC MINERS' LAMP COMPANY (LIMITED).**—During the week a company with the above title, which has been registered with a capital of £80,000 in 39,250 Seven per Cent. Cumulative Preference, 39,250 Ordinary and 1,500 Deferred shares, all of £1 each, has issued a prospectus inviting applications for 31,750 Preference and a like number of Ordinary shares. The prospectus states that the Company has been formed for the purpose of acquiring the various British, foreign and colonial patent rights for the Sussmann electric miners' lamp. The vendors and promoters are "The Electric Exploitation Company," and arrangements have been made with the Edison and Swan Company to manufacture the lamps and to become wholesale agents for its sale in the United Kingdom.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).**—This Company's traffic receipts for the week ended May 15th, after deducting 17 per cent of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,375.

**WEST AFRICAN TELEGRAPH COMPANY (LIMITED).**—The Directors of this Company have declared a final dividend at the rate of 6s. per share, making with the interim dividend already paid a distribution of 4 per cent. for the year.

**WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).**—The estimated traffic receipts of this Company for the half month ended May 15th are £2,476, against £2,798 in the corresponding period of 1895.

## SALES BY AUCTION, &c.

WITHOUT RESERVE.

TO ELECTRIC LIGHTING COMPANIES, ELECTRICIANS, ENGINEERS, AND OTHERS.

**TUESDAY, 2nd JUNE, 1896.**

WHEATLEY KIRK, PRICE and GOULTY have received instructions to

SELL BY PUBLIC AUCTION, WITHOUT RESERVE,

in the Lots of the Catalogue,

**THE ENTIRE CONTENTS**

Of the late Lighting Station of Messrs. THE READING ELECTRIC SUPPLY COMPANY, Limited, situate in

THORN LANE, DUKE STREET, READING, BERKS.

(Owing to this Company having completed their New Central Station),

And which will include: 90 H.P. and 30 H.P. Babcock-Wilcox patent Water-Tube Steam Boilers; Loco. Multitubular Steam Boiler, by Fowler, Leeds; Worthington Pump; 25 I.H.P. Vertical Steam Engine, by Browett and Lindley; 25 and 50 I.H.P. Westinghouse Steam Engine, by Alley and Maclellan; 25 I.H.P. Armington-Sims High-Speed Steam Engine, by Greenwood and Batley; 3 K Type Thomson-Houston Dynamos, series wound; 1 ditto Alternating-Current Dynamo; 1 ditto Composite-wound Dynamo; 18 Transformers, 5 to 125 light, from 300 to 7,500 watts each; 6 M Type, 15 K Type and 47 M Type Thomson-Houston Arc Lamps, 1,200 c.p., 6·8 amperes each; Voltmeters; Ammeters and other effects.

Commencing at Eleven for Twelve o'clock prompt.

May be viewed day preceding and morning of Sale.

Catalogues may be had (gratis) from THE READING ELECTRIC SUPPLY COMPANY (Limited), or from WHEATLEY KIRK, PRICE AND GOULTY, 49, Queen Victoria-street, London, E.C., and Albert-square, Manchester. Telegrams: "Indices" London, and Telephone No. 15,077.

## TENDERS INVITED.

## CITY OF LEEDS.

TO ELECTRICAL ENGINEERS, CONTRACTORS AND OTHERS:—

The COUNCIL require TENDERS for an ELECTRICAL INSTALLATION sufficient for the working by the overhead system of haulage, a double track of Tramway seven miles long. The work will be divided into the following Contracts:—

1. POLES for supporting Trolley Wire.
2. UNDERGROUND CONDUITS and CONDUCTORS.
3. TROLLEY WIRE and attachments.
4. MOTOR CARS.
5. ACCUMULATORS and SWITCHES.
6. STEAM ENGINES.
7. DYNAMOS, SWITCHBOARDS and ACCESSORIES.

Tenders endorsed with the number of the contract must be sent in, addressed to the Town Clerk, Town Hall, Leeds, not later than JUNE 20th next.

Particulars, plans and forms of Tender may be had (on payment of a deposit of £2 2s. for each contract, which will be returned on receipt of a bonâ fide Tender) from the City Engineer, Municipal Buildings, Leeds, or from

Dr. JOHN HOPKINSON, F.R.S.,
5, Victoria-street, Westminster, S.W.

## CITY AND GUILDS OF LONDON INSTITUTE,

SESSION 1896-97.

THE COURSES OF INSTRUCTION IN ENGINEERING AND CHEMISTRY at the Institute's Colleges commence in October, and cover a period of two to three years. The MATRICULATION EXAMINATION of the Central Technical College will be held on September 21st to 24th and the ENTRANCE EXAMINATION of the Day Department of the Technical College, Finsbury, on September 22nd.

**CITY AND GUILDS CENTRAL TECHNICAL COLLEGE**

(Exhibition-road, S.W.), a College for Higher Technical Instruction for Students not under 16 years of age preparing to become Civil, Mechanical or Electrical Engineers, Chemical and other Manufacturers, and Teachers.

THE MATRICULATION EXAMINATION will be held on September 21st to 24th, and the new Session will commence on October 1st.

Professors:—O. Henrici, LL.D., F.R.S. (Mathematics); W. C. Unwin, F.R.S., M.I.C.E. (Civil and Mechanical Engineering); W. E. Ayrton, F.R.S. (Physics and Electrical Engineering); H. E. Armstrong, Ph.D., F.R.S. (Chemistry).

**CITY AND GUILDS TECHNICAL COLLEGE, FINSBURY**

(Leonard-street, City-road, E.C.). The DAY DEPARTMENT provides Courses of Intermediate Instruction for Students not under 14 years of age, preparing to enter Mechanical or Electrical Engineering and Chemical Industries.

THE ENTRANCE EXAMINATION will be held on September 22nd, and the new Session will commence on October 6th.

Professors:—S. P. Thompson, D.Sc., F.R.S. (Electrical Engineering); J. Perry, D.Sc., F.R.S. (Mechanical Engineering); R. Meldola, F.R.S. (Chemistry).

JOHN WATNEY, Hon. Secretary.

City and Guilds of London Institute,
Gresham College, Basinghall-street, E.C.

The SUBSCRIPTION LIST will be OPENED on MONDAY MORNING, 1st JUNE, and will be CLOSED at Four p.m. on Tuesday, 2nd June for LONDON, and at noon on WEDNESDAY, 3rd June, for COUNTRY applications.

# WILLANS & ROBINSON, Limited.

(Registered under the Companies Acts, 1862 to 1890).

**CAPITAL £300,000,** in 30,000 Six Per Cent. Preference Shares of £5 each, and 30,000 Ordinary Shares of £5 each, of which 22,500 Preference Shares and 22,500 Ordinary Shares are issued and fully paid.

## ISSUE OF £100,000 FOUR-AND-A-QUARTER PER CENT. FIRST MORTGAGE DEBENTURE STOCK.

| | | | |
|---|---|---|---|
| Payable on Application | £10 | per £100 | Stock. |
| ,, Allotment | £10 | ,, | ,, |
| ,, 31st July, 1896 | £40 | ,, | ,, |
| ,, 31st January, 1897 | £40 | ,, | ,, |
| | £100 | | |

With option of payment in full on Allotment, under discount at the rate of 2½ per cent per annum, until the appointed dates of payment.

Repayable at par on 31st May, 1921, or, at the option of the Directors, on giving six months notice, at any time after 31st May, 1906, at the rate of £105 per £100 Stock. Interest will accrue from the respective dates of payment, and will be payable on 30th November next, and thenceforward half-yearly on 31st May and 30th November in each year.

TRUSTEES FOR DEBENTURE STOCK HOLDERS.

Lieut-General Sir Richard H. Sankey, R.E., K.C.B., 6, Lowndes-square, S.W.
Frederick Gordon, Bentley Priory, Stanmore, Middlesex.

DIRECTORS.

MARK ROBINSON, M.Inst.C.E., Chairman.
Sir Gilbert A. Clayton-East, Bart.
Captain H. Riall Sankey, R.E. (retired), M.Inst.C.E.

BANKERS.—Lloyds Bank (Limited), Rugby, and 72, Lombard-street, E.C.

AUDITORS.—Cooper Brothers and Co., 14, George-street, Mansion House, E.C.

SOLICITORS.—Farrar and Porter, 2, Wardrobe-place, Queen Victoria-street, E.C.

BROKER.—Hugh Campbell, 16, Tokenhouse-yard, E.C., and Stock Exchange.

SECRETARY.—Charles S. Essex.

Offices and Works—Rugby and Thames Ditton.

Temporary London Office.—14, George-street, Mansion House, E.C.

### PROSPECTUS.

The Debenture Stock is secured by a charge upon the undertaking and upon all the property and assets of the Company. According to the audited Balance-sheet, dated 27th December last, a copy of which is enclosed with the Prospectus, the property and assets amounted on that date to £216,368 7s. 8d., exclusive of goodwill, while the whole indebtedness of the Company amounted to only £12,298 18s. 6d.

The Company's Freehold Properties at Rugby and Thames Ditton have been specifically mortgaged to the Trustees for the Debenture Stock Holders, and the same deed creates a floating charge upon the other property of the Company. The two Freeholds, when the Rugby Works are completed, will stand in the books at about £80,000.

The money to be borrowed is required for completing the new Works at Rugby; for providing additional plant and machinery; and for further working capital.

The business, which is chiefly that of making the well-known Willans Engine, was founded at Thames Ditton in 1881. Owing to its rapid growth, it was converted into a private Limited Company in 1888, and the same cause led to the formation of the present larger Company in 1894; the business has continued to increase rapidly, and has far outgrown the capacity of the Works at Thames Ditton. The horse-power of Engines ordered, in recent years, is as follows:—

| | | | | |
|---|---|---|---|---|
| Old Company | 1891 | 11,100 | indicated | horse-power. |
| | 1892 | 13,800 | ,, | ,, |
| | 1893 | 18,950 | ,, | ,, |
| New Company | 1894 | 26,624 | ,, | ,, |
| | 1895 | 27,883 | ,, | ,, |

The orders in the present year show a great advance upon the above rate of increase. In the first four months of 1896 the horse-power ordered exceeded that for the whole of 1895. Besides the Willans engine, the Company possesses another valuable speciality in the Niclausse water-tube boiler, which it is intended to manufacture upon a large scale at Rugby.

The net profits of the new Company for two years of its existence, including interest paid upon Debentures and Mortgages, taken over from the old Company, all since paid off, have been:—

| | |
|---|---|
| 1894 | £15,708 |
| 1895 | 23,275 |

after carrying £5,737 8s. 5d. and £7,531 13s. 7d. to Depreciation Account in the respective years.

Dividends have been paid each half-year at the rate of Seven per cent. per annum upon the Ordinary Shares, and a Reserve Fund, invested in Securities outside the business, has been created to the amount of £7,646; the sum carried to reserve in 1895 was £5,000. The dividends upon the Ordinary Share capital of the old Company from 1889 to its reconstruction at the end of 1893 averaged 7 per cent., and large sums were reserved in addition.

The Works at Rugby, the buildings for which are far advanced, occupy, with approaches, &c., a portion (about eight acres) of a valuable and well-placed site of 24 acres, adjoining the London and North-Western Railway; the remainder of the land is reserved for extensions. As regards both construction and equipment, the works will be of a very complete and substantial character, and the buildings are laid out to allow of rapid and easy extension upon a pre-arranged plan.

The Trust Deed can be inspected at the Offices of the Solicitors, and copies of the Deed and of the Memorandum and Articles of Association of the Company, together with plans of the Freehold Properties at Rugby and Thames Ditton, can be seen at the Company's Temporary London Office.

Applications for the Stock, in sums being multiples of £10, on the Form enclosed with the Prospectus, accompanied by a remittance of the amount of the deposit on the sums applied for, should be sent to Lloyds Bank (Limited), 72, Lombard-street, E.C. Prospectuses and Forms of Application can be obtained from the London Office, and from all Branch Offices, of Lloyds Bank, as well as from the Company's Solicitors; from the Broker; and from the Secretary of the Company, at either the Thames Ditton or the London Temporary Offices.

If the whole amount applied for by any applicant be not allotted, the amount paid on deposit will be appropriated towards the sum payable on Allotment. In the case of an applicant to whom no Allotment is made, the deposit will be returned in full. Failures by allottees in payment at the due date of any instalment will render the Allotment liable to cancellation and the previous payments to forfeiture.

Certificates will be issued by the Company as soon as possible after the payments are completed.

The Committee of the Stock Exchange has granted an official quotation of the Company's shares, and application will be made in due course for quotation of the present issue.

25th May, 1896.

## APPOINTMENTS VACANT.

### CITY OF LINCOLN.

PUBLIC HEALTH ACT, 1875.

TO ELECTRICAL ENGINEERS.

THE CORPORATION OF LINCOLN (who are intending to construct Works for the supply of Electricity in Lincoln) invite applications for the appointment of ELECTRICAL ENGINEER.

Candidates must have had previous experience in a similar appointment with a Company or Corporation supplying electricity under Parliamentary powers and be competent to design and supervise the construction of the generating station, plant, machinery, cables and appliances necessary to generate and supply electricity for public and private lighting on the low tension direct current system. The Engineer appointed will be required to devote his whole time to the service of the Corporation.

The salary will be at the rate of £300 per annum.

Particulars of Duties, &c., and Forms upon which applications must be made may be obtained from the undersigned, to whom applications (endorsed "Electrical Engineer") must be sent not later than Saturday, the 6th day of June, 1896.

Canvassing members of the Council will disqualify a candidate.

St. Peter's Churchyard, Silver-street, Lincoln, 18th May, 1896.

H. K. HEBB, Clerk of the Urban Sanitary Authority and Deputy Town Clerk.

### NORTHERN POLYTECHNIC INSTITUTE.

THE GOVERNORS invite APPLICATIONS for the appointment of HEAD of the DEPARTMENT of PHYSICS and ELECTRICAL ENGINEERING; commencing salary £250 per annum.

The appointment will date from September 29th, 1896, but the candidate appointed will be expected in the meantime to consult with the Principal as to the equipment and organisation of the Department.

Conditions of appointment, and forms of application, may be obtained from the Secretary, at the Institute, Holloway-road, London, N.

Applications, accompanied by copies of recent testimonials and the names of three referees, to be sent in to the PRINCIPAL, not later than June 1st, 1896.

E. GRIFFITHS, Secretary.

A COLONIAL FIRM with OFFICES and WAREHOUSES in NEW ZEALAND and AGENCIES thoughout AUSTRALASIA, is open to REPRESENT a few good ENGLISH and CONTINENTAL HOUSES in ELECTRICAL MACHINERY and SUPPLIES (Mining Machinery preferred).

TRAVELLERS CONSTANTLY AT WORK.

*(Sole Agencies only accepted.)*

Address: HADLEY & CO., Auckland, New Zealand.

## AGENTS WANTED

For the Home and Export Trades to REPRESENT a celebrated German Manufacturing FIRM of DYNAMOS and ELECTRO-MOTORS.

Liberal Commission and most Favourable Terms to energetic and competent men.

Address: E. O. 281, care of RUDOLF MOSSE, Dresden.

## SITUATIONS VACANT AND WANTED.

DRAUGHTSMAN (junior) WANTED, accustomed to preparing Engineering Drawings for re-production by photo process. State age, qualifications, experience, and salary required to:—"PRESS," *Electrician* Office, 1, 2 and 3, Salisbury-court, Fleet-street, London.

PARTNER WANTED by experienced Electrical Engineering Manager with a valuable and large business connection. Capital required £2,000.—Apply, 2196, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ADVERTISER (nearly 16) wants to enter Electrical Engineering Works as PUPIL. Good references given and required.—Address, 'MARTIN," 32, Silverlands-road, Silverhill, St. Leonards-on-Sea.

ELECTRICAL ENGINEER seeks RE-ENGAGEMENT; used to practical work and installation, or would take a post as Improver, without salary, in a good electrical firm.—"E. H. T.," 92, Warwick-gardens, Kensington, London, W.

ELECTRICAL ENGINEER seeks ENGAGEMENT, capable of estimating for and carrying out electrical wiring. Good general experience, moderate salary.—Address, "G. S.", *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ENGINEER, 9 years' experience in factory, installation, and station work, used to estimating and designing, seeks ENGAGEMENT in works office. Highest references.—2213, *Electrician* Office, Salisbury-court, Fleet-st.

WANTED, situation as INVENTOR'S MODEL MAKER, used to small mechanical work.—Address, W. WATSON, Green Dragon Hotel, Beverley.

**ELECTRIC LIGHTING AND POWER DISTRIBUTION.** An Elementary Manual on Electrical Engineering, suitable for Students preparing for the Preliminary and Ordinary Grade Examinations of the City and Guilds of London Institute. By W. PERREN MAYCOCK, M.I.E.E. Third Edition (in Two Volumes). Vol. I., with numerous Questions and Exercises, including all those set for the Preliminary and Ordinary Grade Examinations since 1890. 231 Illustrations, Index, and Ruled Pages for Notes.

CONDENSED TABLE OF CONTENTS OF VOLUME I.

CHAP. I.—Force, Mass, Work, Power, Energy, Units, &c.
CHAP. II.—Electricity, Conductance, Resistance, Quantity, Current, B. o. T. Unit, Circuit, Ohm's Law, Electrical Work and Power, Joule's Law, Heat Units, Condensers, &c.
CHAP. III.—Fall of Potential, Effects of a Current, Right-Hand Rules, Magnetism, Magnets for Direct and Alternating Currents, &c.
CHAP. IV.—Induction of Currents, Experiments in Electromagnetic Induction, Laws, Self and Mutual Induction, Attraction and Repulsion of Currents, &c.
CHAP. V.—Electric Bell Fitting, Indicators, Relays, Circuit Diagrams, &c.
CHAP. VI.—Magnetic Properties of Materials, the Magnetic Circuit, Curves, Measurement of H, M, I, B, and $\mu$, Susceptibility, Hysteresis, &c., &c.
CHAP. VII.—Board of Trade Standards, Measurement of Resistance, Wheatstone and Slide-Wire Bridges, Galvanometers, Voltmeters, Ammeters, Ohmmeters, Wattmeters, Recording Apparatus. The Measuring Instruments of Cardew, Ayrton and Perry, Holden, Kelvin, Swinburne, Evershed, Paterson and Cooper, Schuckert, Muirhead, Siemens, &c.
CHAP. VIII.—Principle of the Dynamo, Armatures, Armature Cores, Winding of Armatures, Field Magnets, Excitation, Sparking of Dynamos, Construction of Commutators, Rockers, Brush-Holders, Brushes, &c., &c.
CHAP. IX.—Direct-Current Dynamos. Illustrations and Descriptions of the Machines of Kapp, Mather and Platt, Siemens, Goolden, Laurence-Scott, Parker, Ernest Scott and Mountain, Joel, Crompton, Rankin-Kennedy, Lahmeyer, Brush, Mavor and Coulson, Jackson, Thomson-Houston; and Details thereof. INDEX TO VOLUME I.

**WHITTAKER & CO., 2, White Hart Street, Paternoster Square, London.**

## WANTED, and FOR SALE.

PLATINUM UTENSILS, SCRAP, LAMP TOPS.—Best prices given by Derby and Co., 44, Clerkenwell-road, London, E.C. N.B.—Platinum sold

DYNAMO, 50 volts 7 amperes; vertical type. Weighs about 1cwt; runs well as motor. £6. 10s.—29, Roupell-street, S.E., near Waterloo Station.

FOR SALE, 20in. by 42in. high-class, bright expansive HORIZONTAL STEAM ENGINE, 10ft. 6in. turned belt Fly Wheel, variable expansion, governors, and usual appliances of the highest class of workmanship and finish; adapted for mill, factory, or dynamo driving. Practically new, and will be sold to an immediate purchaser at less than half cost price.—For specification, &c., address JAMES LIGHT, Wolverhampton.

ACCUMULATOR CHARGING.—C. H. CATHCART and CO., having plant specially adapted for this purpose, Charge Cells of all sizes promptly, thoroughly and cheaply. Terms on application. Accumulators on Hire for temporary lighting, experimental uses, &c.—3, Dorset-buildings, Salisbury-square, Fleet-street, E.C. (Telephone No. 65,266.)

ELECTRICIANS.—NOTICE to EMPLOYERS.—Please note we have a number of First-Class ELECTRICAL MEN upon our Books. Kindly send us particulars of any VACANCIES you may have. We can introduce you, free of charge, to the best men now at liberty.

Address, CHAS. RICHARDSON and CO., Engineers' Bureau, 342, Strand, London, W.C

PARTNERSHIPS.—ELECTRICAL ENGINEERS and others WANTING PARTNERS, or wishing to SELL, can be introduced to Clients with Capital; and GENTLEMEN Seeking Investments can obtain personally (or through their solicitors) particulars of bona-fide OPENINGS. Strictest confidence observed.—Address, CHAS. RICHARDSON and CO., 342, Strand, London, W.C.

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 941. [Vol. XXXVII. No. 5.] FRIDAY, MAY 29, 1896. PRICE SIXPENCE.

## NOTES.

In another column will be found the alterations in the Articles of Association of the Institution of Electrical Engineers, which the Council propose to submit to the Members at the Special General Meeting to be held this afternoon. It would certainly be possible to suggest still further improvements; but the alterations, as they stand, are a notable and generous concession to the demands of those who, like ourselves, have long advocated a liberal measure of reform in the machinery of the Institution.

In the future there will be a regular and sufficiently rapid flow of members through the Council chamber; greater opportunity will be afforded to add to the Council's annual list and to discuss the affairs of the Institution; and, lastly, the voting power of Past-Presidents will be reduced to a reasonable amount. To our mind the way in which this last and most important reform has been achieved reflects great credit on the statesmanship and good feeling of the Council. The complete disfranchisement of a particular section of the community always savours somewhat of red-revolution; it invariably causes bad blood and paves the way for reaction. The Council avoids all this by the simple and politic process of giving votes only to the four senior Past-Presidents present at any meeting of Council. The proviso by which the immediate President retains his vote for a year is also an excellent one. The rule that when candidates for the Council are nominated by outside members their names and those of their supporters shall be shown separately, is to be commended; it will tend to prevent unnecessary and undesirable additions to the house list, and, moreover, Council cannot, in common fairness, be expected to father other than their own recommendations.

On the other hand, it is to be regretted that it has not been thought expedient to confine the proceedings at the Annual General Meeting solely to the reception of the Annual Report of Council, to the passing of the accounts and to the consideration of the affairs of the Institution. In peaceful times there might not, indeed, be much to say, but we believe that if members knew one evening every year would be allotted to the amicable discussion of questions concerning the management and welfare of the Institution, many valuable suggestions would be forthcoming, and many grievances would be nipped in the bud. It is pleasant to think that good sense has prevailed, and an unedifying wrangle been avoided.

As the time approaches when the scientific and technical societies will commence their summer vacation, increasing activity in electrical matters prevails among them. What promised at the beginning to be a somewhat dull session has proved to have been full of interesting and useful matter relative to electrical theory and practice. On Friday last, at the meeting of the Physical Society, no less than three electrical Papers were read, while later in the same day Prof. EWING delivered before the Royal Institution his popular lecture on "Hysteresis."

A LONG string of topical jokes served to introduce Prof. EWING'S *bizarre* subject. There had been, he said, an all-night sitting of the House of Commons and an all-night standing of the great Wheel, both of which were due to a form of hysteresis —internal friction. There had been "angelic whisperings" into his ear previously to the lecture, by a lady who was curious to know whether the lecture was to be on "hysterics, hypnotism and whisperings of the angel GABRIEL," but he regretted that he had heard no angelic whisperings—since she ceased to speak. In a recent lecture Prof. KENNEDY had said there was hysteresis in everything, while only a few days ago the editor of an art magazine had declared he could not find "hysteresis" anywhere, not even in OGILVIE'S dictionary—whether of the two was correct? And since joking served so well to start his lecture, Prof. EWING decided to be humorous at its close, when he told his audience that "if while he had been engaged in delivering one difficult sentence they had been occupied in trying to understand the one which had preceded it, they were but exhibiting in their own minds a form of—hysteresis!"

BUT though beginning and ending in this light and happy vein of humour, the lecture was by no means devoid of solid and instructive matter. A subject difficult to treat of in a popular manner was handled with masterly care and discretion, the mysteries of the B – H curve being unveiled in language that must have been intelligible to even a non-technical audience. Or, if language failed to help them, there was the actual curve itself on the wall, outlined by a curve-tracer of dazzling light, to say nothing of the colony of wobbling little magnets whose shadows the lantern threw upon the screen. Indeed, the experimental illustrations afforded by Prof. EWING'S ingenious instruments were both numerous and effective. Of special interest was the experiment which reproduced the conditions, first pointed out by

Digitized by Google

SWINBURNE and subsequently verified by BAILY, under which a mass of magnetic metal, rotating in a magnetic field, does not exhibit hysteresis. Nor, though the lecture was in the main directed to the unscientific and non-technical hearer, were the leaders of science who were present allowed to go empty away; for Prof. EWING hazarded a hypothesis, not altogether new, which might be expected to give them plenty of food for reflection, viz., that all friction is in the nature of hysteresis arising from the breaking up and rearrangement of molecular chains, the forces binding which together are not magnetic but electrostatic. For ourselves, we are more impressed with the ingenuity of the suggestion than convinced of its truth.

PROBABLY the most important matter brought before the Physical Society on Friday last was the Paper by Prof. VIRIAMU JONES on "The Magnetic Field due to an Elliptical Current at a Point in the Plane of the Ellipse." The Paper itself, being of a mathematical character, was not read; but one of its most important consequences was discussed, viz., that by the aid of the correction for ellipticity which Prof. JONES thereby had been enabled to apply to his method of evaluating the ohm, the international ohm had been brought more nearly into accord with the true ohm. The original evaluation obtained by Prof. JONES was 106·309cm. of mercury, while the correction now applied reduced the length of the mercury column to 106·302cm. This practical outcome of the Paper is sufficient answer to Mr. WALKER'S absurd statement that the Paper was unfitted for presentation to the Physical Society, and should have been taken to the Mathematical Society. There is an obvious difference between physical research by the aid of mathematics and purely mathematical research.

MR. APPLEYARD'S Paper on "Dielectrics" chiefly interested the members present on account of the use of Mr. PRICE'S guard ring which had been made in the investigations described. In order to eliminate error due to surface leakage over the core end in testing a length of cable, a guard ring, placed so as to intercept the surface leakage, was used. Prof. AYRTON pointed out that when this ingenious device was adopted, it was no longer necessary to prepare the cable end in the careful manner that had been the time-honoured custom, and thus a great deal of time might be saved when making cable tests. Some discussion arose as to the best method of preparing a cable end when a guard ring is not used. Prof. AYRTON stated that it had been formerly his custom, as we know it also has been the custom in other places, to cover the well cut end with filtered paraffin wax; but Mr. APPLEYARD preferred to wash the insulation with naphtha, and not to apply any paraffin wax. Fortunately, it does not much matter which of these methods is the better, for Mr. PRICE'S guard ring is so efficacious and so easily and quickly used that we doubt if anyone would now perform a test on a cable end without employing it.

WE transcribe elsewhere certain portions of an estimate of the manufacturing cost of calcium carbide, based on data obtained under conditions precluding biassed observation, at the Willson Aluminium Company's works, at Spray, Rockingham County, North Carolina. The figure arrived at, viz., £7. 4s. per ton of crude calcium carbide, yielding about 80 per cent. of its theoretical output of acetylene, is a good deal more favourable than any previous estimate having a similar right to be considered trustworthy, while it is correspondingly less favourable than the glowing figures freely published on very slender authority a few months back. Any enterprising Briton intending to manufacture acetylene, and confident of a market at the rates implied by this estimate, should study the report in full, and especially consider those relations of cost of power to cost of raw materials which are there fully worked out and even crystallised into empirical formulæ. The calculation of the cost of generating, purifying, collecting and compressing the ultimate product acetylene still awaits the advent of a competent and unprejudiced observer possessed of the necessary opportunities. Meanwhile, the fact announced in a companion article that the calcium carbide works at Niagara Falls have been started, and that it is expected to be able to supply the carbide at $23 per ton, leads us to hope that this further information will soon be available.

SOME curious results have recently been obtained by Mr. T. A. VAUGHTON with an electric current passing through a light cantilever spring, making an electrical contact at the point of support. In certain circumstances, which are stated in the account of these experiments Mr. VAUGHTON contributes to our columns this week, when the spring is artificially set in vibration the passage of an electric current maintains it in vibratory motion. The action appears to be analogous to that of the well-known Trevelyan rocker, which consists in a heated mass of metal of such a shape that when placed on a surface which will rapidly conduct away the heat it is thrown into vigorous rocking, and emits a musical note. There is also, we suspect, some connection between the curious phenomenon investigated by Mr. VAUGHTON and the remarkable change in friction at an electrical contact between certain substances, which was first detected by EDISON, and used by him in his chalk telephone receiver.

**Obituary.**—Mr. Francis Rudall, who for many years was the telegraphic engineer to the London, Chatham and Dover Railway, died on Tuesday, May 19th, at the age of 69, at his residence at Anerley.

**The P.Q. Atlantic Cable.**—The "Seine" has restored communication across the Atlantic by this cable. The deep water repair was completed on Friday last, and we understand that the "Seine" is now on her way home.

| **Cable Interruptions.** | *Date of Interruption.* |
|---|---|
| Puerto Plata—Martinique ..... ..... | Dec. 19, 1895. |
| Ceara—Maranham ..... | April 28, 1896. |
| Monte Alegre—Santarem ..... ..... | May 5, 1896. |

**Lectures at the Berlin Industrial Exhibition.**—The administration of the Berlin Exhibition, under the presidency of Dr. Bödiker, has made arrangements with several well-known scientists to deliver lectures every evening throughout the exhibition season, with the exception of Sundays. From a full list of the lectures, published by the *Elektrotechnische Zeitschrift* this week, we find that a very wide range of subjects is covered.

**Bavarian Exhibition at Nuremberg.**—As at the other German exhibitions electricity plays an important part in the Nuremberg Exhibition. Besides the lighting of the buildings and the grounds several interesting electrical exhibits by Bavarian manufacturers are on view. A three-phase trans-

Digitized by Google

mission plant, running at 41,000 volts, erected by Messrs. Schuckert and Co., is shown at work. A continuous-current transmission plant at 3,000 volts is run with a single generator. The Pollak system of charging accumulators by alternating currents is shown on a large scale. A Nuremberg toy factory shows the wholesale manufacture of toys with electrically-driven tools.

**Electric Mountain Railway at Zermatt.**—A company has been started for the construction of an electric rack railway from Zermatt up the Gornergrat. This eminence is about 10,500ft. high, and is a well-known point for obtaining a good view of the surrounding Alps. The railway will be six miles long, and will have an average gradient of 15 per cent. and a maximum gradient of 20 per cent. Each train is to consist of two cars and to carry 100 passengers. The time for either journey will be two hours. Power will be obtained from the Findelen river. The total cost of the line is estimated to be about £140,000, and the opening of the line is expected to take place in 1898.

**The New Paris-London Telephone Line.**—We are able to state that the negotiations between the British and French Governments for the formation of a new telephone line between London and Paris are approaching completion. The route selected for the new line will probably not differ substantially from that of the existing telephone line; and, as is now occasionally done on the present system, the new system will when necessary be used for simultaneous telegraphic and telephonic service. It is stated that the French Government has entered into an arrangement with the Paris Stock Exchange, by which the latter undertakes to pay the French share of the costs of the system.

**Electric Traction in Germany.**—Electric traction on the overhead system is making rapid progress in Germany. Not a week passes but we read of one or two new lines being opened or old horse lines converted into electric lines. It is not surprising that tramway companies and municipalities are adopting electric traction, seeing what profit has already been obtained with it. Several of the concerns are now paying dividends of 8 and 10 per cent. A few days ago an electric tramway was opened at Kiel. The total length of the line is about 12 miles, and there are to be 35 motor cars and 18 trailers in the full service. The system employed in this instance is the overhead trolley of the Allgemeine Electricitäts Gesellschaft.

**Telephone Facilities on Tramways.**—A simple system of telephone communication between tramcars and the superintendent's office has, says the *Electric Railway Gazette* of New York, been put into operation on the Bangor, Orono and Old-town Railway, Bangor, America. It consists of hanging a telephone wire alongside the trolley wire a sufficient distance away to insure immunity from accidental contact between the two. Each car is provided with a set of telephone instruments, which may be connected across from the trolley to the wheels when desired, but which are, of course, normally cut out. When a conductor desires to communicate with the office the car is stopped, the trolley is transferred from its own wire to the telephone wires alongside, and the telephone set is put in circuit.

**Gas Accident at Southsea.**—The Portsmouth Electric Lighting Committee has received a report from Major Cardew relative to the recent accident when a cabman was injured by an electric shock from a lamp column. Major Cardew reported that he had examined the column and switch and found them in perfect order, the explosion being due to an escape of gas. There was no electric leak, but gas had escaped from a pipe which was found to be broken in two, and passed through the ducts to the column. When the arc light was turned out, and the incandescent lamps switched on, the gas exploded, and this was the cause of the accident. The injured man showed signs of electric shock, the muscles of his right arm being contracted; and Major Cardew having laid the matter before Lord Kelvin, the reply was that flame was a conductor of electricity, and that the current had been communicated to the man in this way.

**The Specific Heat of Electrolytic Solutions.**—An interesting investigation on the specific heat of solutions has, says *Nature*, been given by Herr G. Tammann in the *Zeitschrift für Physikalische Chemie*. It is well known that weak solutions of certain electrolytes have a smaller capacity for heat than the water present in them possessed previously to the introduction of the salt, and the object of the investigation is to establish a connection between this phenomenon and the contraction of volume which accompanies the process of solution. This contraction has often been accounted for by the hypothesis of a certain internal molecular pressure. Herr Tammann calculates the specific heat of the water present in a number of solutions of this class on the supposition that their pressure is the *increased* pressure postulated by the above theory, and he also calculates the specific heat of the dissolved substance, that of the mixture being deduced by adding the thermal capacities of the two components. The theoretical values thus obtained are found to agree closely with the values experimentally found by observing the solutions themselves, and it is inferred that contraction is the sole cause of the diminution of specific heat arising from the presence of the dissolved matter.

**Cable v. Electric Traction.**—Some of the disadvantages of cable traction, says the *Electric Railway Gazette*, of New York, have been clearly demonstrated by a recent accident on the Broadway cable line. "A strand in the cable broke and promptly caught in the grip die of a neighbouring car, which at once became a runaway. The cable was stopped, and after a ten-minutes interval the relief cable was adjusted and traffic resumed. Then another strand broke and caught the grip of the nearest car with unfailing precision. The car proceeded up town, smashing the smaller vehicles and pushing aside the larger ones. As it continued in its destructive career it accumulated both cars and momentum. Fully seven cars were incorporated in this battering ram before the cable was stopped. The street was strewn for blocks with wreckage. The relief cable was a new one, and no such accident was anticipated. No one was killed, but many were injured and much damage to property was caused. It is difficult to imagine an equally destructive accident on the lines of an electric traction system. With every improbable occurrence exaggerated to the utmost, this common cable road accident stands unrivalled."

**Lord Kelvin's Jubilee.**—The following is stated by *Nature* to be the programme of the jubilee celebrations of Lord Kelvin's professoriate at Glasgow. On the evening of Monday, June 15th, at 8:30 p.m., the University will give a conversazione, when there will be an exhibit of Lord Kelvin's inventions. On Tuesday, June 16th, addresses will be presented to Lord Kelvin by delegates from home and foreign University bodies, from several of the learned societies of which he is a member, from student delegates from other universities, and from the students and graduates of the University of Glasgow. It is expected that the honorary degree of LL.D. will be conferred on the same day on several of the distinguished foreign visitors. On Tuesday evening, June 16th, the city will give a banquet to Lord Kelvin, to which the visitors who have come to do him honour have been invited. On Wednesday, June 17th, the senate of the University will invite the visitors of the University staff to sail down the Clyde. The students of the University also invite the student delegates from other Universities to a similar trip. Representative scientific men—about 50 in number—from America and the British colonies, and from all the European countries, and about 150 from the United Kingdom have signified their intention to the present.

**The Beauchamp Tower Search-Light Platform.**—Admiral Henry Boys presided recently at a meeting held at the Royal United Service Institution, when Mr. Tower described his hydraulic apparatus for providing a steady platform at sea for search-lights, &c. Those present included Vice-Admiral Lord Charles Scott, Captain Count Loratelli, Mr. Brunel and Mr. Thornycroft. The first practical machine was fitted up on a small steam yacht, 50ft. long and 11ft. beam, and was subjected to a laborious course of experiment, extending over about two years. It was experimented with by the officers of Her Majesty's ship "Vernon" as a means of mounting search-lights, and by the officers of Her Majesty's ship "Excellent" as a means of mounting machine guns. In both cases their reports showed that the machine answered the purpose for which it was designed perfectly. After these experiments, a machine for mounting

Digitized by Google

a 24in. search-light projector was ordered by the Admiralty to be fitted to Her Majesty's gunboat "Bloodhound," tender to Her Majesty's ship "Vernon," for further experiment, which showed that the machine could be depended on to keep a search-light ray absolutely steady on a small vessel in a heavy sea, and further favourable reports were sent to the Admiralty on the subject. Since then Sir W. G. Armstrong, Mitchell and Co. had taken up the manufacture, and were fitting the device to the torpedo-destroyers "Swordfish" and "Spitfire," which they were constructing for the Navy. They were also supplying Tower platforms to the order of the Chilian Government for a cruiser building at Elswick.

**Gas-Driven Electric Supply Stations.**—Commenting on our last week's editorial notes on the recently published accounts of the Belfast gas engine electric supply station, in which we analysed these accounts, the *Journal of Gas Lighting* publishes a long leading article, in the course of which it makes the following observations:—

> How pleased and proud Denny Lane would be, were he alive to see this justification of his views in this regard! These results show that where gas can be had for anything like the same price, it is far better for a small electric lighting undertaking to try gas power, at any rate for a start, than to put down steam-engines, which cannot possibly be worked at first, if ever, at an economical load. The difficulty of the "peak of the load" will always remain in the path of small electric lighting companies; and, unless satisfactorily negotiated, it will effectually bar their way to dividends. The gas engine is the very thing to remove this trouble. It is only to turn the gas key, and the power is there at the instant; while a suitable accumulator will fill up the gap by day and after midnight. It may be said, of course, that this is to throw the burden of the load factor upon the gas supply. But a little thing like this will not make the slightest difference to a gas undertaking, the proprietors of which would as soon sell gas to an electric lighting company as to any other consumer. We are not now, and we never have been, in favour of a gas company venturing upon an electric lighting branch department. All the same, there is no reason why the company should not offer every facility to those who provide or use electricity for lighting purposes, in the form of cheap gas and plenty of it. It is painful to see a corporation or private electric lighting station standing almost idle for the greater portion of the 24 hours, or working under ruinous conditions, while the gas-main that passes by the doors has within it the potentiality of curing the worst of the electricians' troubles. Why should a small county town—like Kingston-on-Thames, for instance—go to the ridiculous expense of a steam-power electricity generating station, with little or nothing for it to do, while the gas company could supply all the power needed for trying the experiment of whether the district needs electric lighting at the minimum of expense to the unfortunate rate-payers? Truly, the history of municipal enterprise in the way of electricity supply furnishes still another illustration of the truth of the exclamation: "With what little wisdom are we governed!"

**The E.M.F. of the Clark Cell.**—The February number of the *Journal de Physique* contains a Paper, by M. C. Limb, on the determination of the electromotive force of a Clark cell in absolute measure. Instead of adopting the usual method, which is to compare the difference of potential at the ends of a known resistance when traversed by a known current with that of the cell, the author, says *Nature*, has adopted a novel method which is independent of the units of current and resistance. A magnet is rotated inside a long helix about an axis perpendicular both to its own magnetic axis and the axis of the coil. The magnetic moment of the magnet is determined by Gauss's method. If H is the field which would be produced at the centre of the long coil if the spirals were traversed by unit current, $\omega$ the angular velocity of the magnet and M its magnetic moment, then the maximum value of the electromotive force induced in the coil will be $H M \omega$. A correction has to be applied on account of the finite length of the coil which involves the distance between the poles of the magnet. The angular velocity is measured by simultaneously registering the turns made by the magnet and the beats of a seconds pendulum, the velocity being maintained constant by a specially-designed tachyometer. By means of a commutator fixed to the axle of the magnet, the circuit of the coil is only closed at the moment when the induced electromotive force is a maximum. This maximum electromotive force is compared with that of the cell by means of a modified form of Clark potentiometer, a Lippmann capillary electrometer being employed to indicate when the balance is secured. This electrometer is capable of indicating a difference of potential of 0·0005 volt. The Clark cell was of the H pattern, and the author gives as his final result for the electromotive force of this form of cell at 0°C. the number 1·4535. The number obtained by Lord Rayleigh was 1·4527 volts.

**An American Combined Gas and Electric Fitting Patent.**—Judge Coxe, says the *Electrical World*, gave judgment on March 10th in the case of George Maitland *v.* Archer and Pancoast, which sustains the Stieringer patent for improvements in electrical fixtures. The point at issue was the validity of a patent claim for an electric light fixture, wholly or largely of metal, provided with insulating conducting wires conveying current to lamps thereon, in combination with an insulating joint at the upper end of the fixture. Judge Coxe in his opinion says that he is convinced that Stieringer was the first to make the use of gas chandeliers a practical success in the art of electric lighting; that while prior structures were not only dangerous, but awkward and ungainly, that of Stieringer is absolutely safe, and at the same time preserves the symmetry and graceful contour of the fixture. "When," he says, "the conditions surrounding the genesis of electric lighting are remembered, it can hardly be denied that the man who yoked the old with the new, and fully developed the art of electric lighting, was something more than a mechanic. It is plain that he who utilised for electric lighting the expensive and intricate gas light systems then existing, and the fixtures which embodied a multitude of graceful designs, took a long step forward. He made electric lighting cheap, convenient, simple and safe. . . . A number of accomplished inventors were at work on this very problem. They accomplished nothing. Stieringer succeeded. It is not an unreasonable presumption that one who succeeds in doing what so accomplished an inventor as Edison failed to do is on a distinctly higher plane than a mechanic. Not only did Edison fail himself, but he was among the first to acknowledge the merits of the invention, practically as well as theoretically, for his firm took out a licence under Stieringer's patent." The opinion proceeds to say that Stieringer's joint, located at the ceiling, seems to be regarded as one of the absolutely essential features, where an internally-wired metal fixture is used. The court defines the combination in suit as having the following elements:—First, a metallic fixture for electric lights, containing insulated conducting wires; second, an insulated joint, located at the upper or inner end of the fixture, and having metallic coupling portions and an intermediate section of insulating material; third, the grounded piping of a house, by which the chandelier is thus supported. The decision is that this claim is infringed, and the complainant is entitled to the usual decree.

**Contemporary Electrical Science.**—A simple and ingenious device for measuring the frequency of an alternating current is described by T. Wulf in the *Wiener Berichte*. A Mariotte flask with a narrow tube is mounted on an iron stand. The water flows out through the tube in a fine jet. An electromagnet excited by the current is placed close to the iron stand. This vibrates with each alternation, and breaks up the jet into a series of drops varying in size according to the frequency. By rotating a stroboscopic disc in front of the jet a speed may be found at which the drops appear stationary. This speed measures the frequency.——M. Ch. Margot describes a process for copper-plating aluminium in the *Archives des Sciences Physiques et Naturelles*. The difficulty has always lain in overcoming the resistance of the alumina formed. The plate is cleaned in a warm solution of an alkaline carbonate. This makes it rough and porous. It is then washed in running water, dipped in a hot 5 per cent. solution of hydrochloric acid, washed and dipped into a dilute acidulated solution of copper sulphate until it has a slight coating of copper. It is washed again, and dipped once more into the copper sulphate, and a current is sent through the solution. The metal then takes a coating of copper of any thickness desired.——A Bonn physicist, rejoicing in the name of Krummenacker, has investigated the surface resistance of glass. An abstract of his dissertation appears in *Wiedemann's Beiblätter*. Surface resistance, he finds, depends upon the moisture of the surrounding air, and this can be governed by placing the glass in a closed vessel over sulphuric acid of various degrees of concentration. Employing Siemens's condenser method, he obtained for the surface resistance of 1sq. cm. of lead glass 6,000 megohms. For soda glass it was 700 megohms. Glass left to solidify was less conducting than polished glass. The highest surface conductivity was obtained with fractured and with ground glass.

## ELECTROMAGNETIC THEORY.—LXXXVI.*

BY OLIVER HEAVISIDE.

(*Continued from page 849, Vol. XXXVI.*)

§ 346. The preceding electrical reasoning will enable us to understand the results produced in the formulæ when the inner boundary is shifted to the origin. At the same time they do not absolve us from making the examination, because without it we cannot say what special form is assumed when the terminal condition is potent.

In the original formula (22) put $\lambda=0$. There are three results. If $n$ is not less than 1, we get $a=-\sin m\pi$. If $n$ is not greater than $-1$, we get $a=+\sin m\pi$. In the intermediate case, when $n$ is between $-1$ and $+1$, we get

$$a=\sin m\pi\,\frac{1-u}{1+u},\quad\text{where}\quad u=\frac{Z_0q}{Z}\left(\frac{2}{q}\right)^n\frac{\lfloor m}{\lfloor -m-1}. \tag{78}$$

That is, in the first case the $x$ function in (22) reduces to $2I_{mx}$; but in the second case to $2I_{-mx}$; whilst in the intermediate case $Z_0$ remains potent, and $a$ has the special value shown in the last equation.

From the above may be derived the changes in the other formulæ, or they may be done separately. Thus, in the alternative formulæ (32) and (50), which are connected by

$$-f=\frac{r\sin m\pi}{1+r},\qquad -g=\frac{s\sin m\pi}{1+s}, \tag{79}$$

we have $r=0$ when $n>1$; $r=\infty$ when $n<-1$, and $r=u^{-1}$ intermediately, $u$ being as in (78). Therefore $s=0$, or $g=0$, is the reduced form of the determinantal equation when $n>1$, or $b+\sin m\pi=0$, or

$$(I_m+BI_{m+1})_e=0,\quad\text{or}\quad(J_m-B'J_{m+1})_e=0. \tag{80}$$

Also, when $n<-1$, the determinantal equation is $s=\infty$, or $g+\sin m\pi=0$, or $b-\sin m\pi=0$; or

$$(I_{-m}+BI_{-m-1})_e=0,\quad\text{or}\quad(J_{-m}+B'J_{-m-1})_e=0. \tag{81}$$

As regards $a$ in (61) when $\lambda=0$, first we have $a=0$ when $n>1$. Then $a=-\tan m\pi$, when $n<-1$. Intermediately

$$a=\frac{-\sin m\pi}{\cos m\pi+v},\quad\text{where}\quad v=\frac{Z_0s}{Z}\left(\frac{2}{s}\right)^n\frac{\lfloor m}{\lfloor -m-1}. \tag{82}$$

So, in the first case, we have

$$V_1=\frac{\frac12\pi Zh}{(xy)^m}J_{mx}\left(G_{my}-\frac{J_{my}}{\beta}\right),\qquad(n>1) \tag{83}$$

and $\beta=0$ is the determinantal equation of normal systems; the same as (80).

In the second case the $x$ function is $J_{-mx}/\cos m\pi$, and

$$V_1=\frac{\frac12\pi Zh}{(xy)^m}\,\frac{J_{-mx}}{\cos m\pi}\,\frac{\beta G_{my}-J_{my}}{\beta+\tan m\pi},\qquad(n<-1) \tag{84}$$

whilst the determinantal equation is equivalent to (81).

Intermediately, using $a$ as in (82), the determinantal equation $a=\beta$ is represented by

$$(J_{-m}+B'J_{-m-1})_e+v(J_m-B'J_{m+1})_e=0, \tag{85}$$

where $v$ is as in (82), and $B'$ is $Z_1s^n/Z$, as before.

As a test of avoidance of error in the way of wrong factors, make $n=0$, or $m=-\frac12$ in the last equation. It reduces to

$$\tan sl\,(1-Z_0Z_1s^2/Z^2)+Z_1s/Z+Z_0s/Z=0. \tag{86}$$

Comparing with (75), § 293, we find proper agreement, allowing for the present generalised meanings of Z and $s$ compared with their meanings in that place.

The peculiarities of infinite resistance or permittance at the origin with suitable values of $n$ place restrictions upon the restraints possible. The source at $y$ cannot raise the potential at the origin above zero when $n$ equals or is less than $-1$. We may, however, also have the potential zero there when $n$ is greater, namely, up to just less than $+1$, but then it must be done by external restraint, through $Z_0=0$, being equivalent to a short circuit if a pair of conductors be in question. But when $n=$ or $>1$ it is no use trying to make the potential vanish.

Similarly, the current at the origin due to the source at $y$ vanishes naturally when $n=$ or $>1$. We can also make it vanish there when $n$ is less, down to just over $-1$, by external restraint, through $Z_0=\infty$. It is equivalent to a disconnection in the case of wires. But it is no use trying to make the current vanish when $n$ equals or is less than $-1$.

Equation (85) only applies when $n$ is between $-1$ and $+1$, but it harmonises with the proper forms outside those limits. Thus $v$ vanishes when $Z_0$ does, which makes the potential be zero terminally, provided $n$ is intermediate, and then (85) reduces to (80). Also, if $Z_0$ is infinite (85) reduces to (81), the other form.

If we impose the condition $V_2=0$ at $l$, then $B'=0$, and (85) becomes

$$(J_{-m}+vJ_m)_e=0,\quad(-1>m>0\ \mathrm{Km}<0). \tag{87}$$

If, in addition, $V_1=0$ at origin by external restraint, then $J_{-ml}=0$ is the determinantal equation. This is replaced by $J_{ml}=0$ if the current is zero at the origin by external restraint.

§ 347. The development in Bessel series when $h$ is steady or impulsive is to be done in just the same way as for Fourier series, which department has been somewhat elaborated. So little need be said about it. First find the final steady state, when there is one, as is nearly always the case in practical problems. Let this be $V_0$. Then apply the $p(d/dp)$ operation to the denominator $a-\beta$ (or other form) in the operational solution, according to the expansion theorem. Thus, using (61), and supposing $h$ to be steady, beginning when $t=0$, we expand it to

$$V_1=V_0+\sum\frac{\frac12\pi Zh}{(xy)^m}\,\frac{(J_m-aG_m)_x(J_m-\beta G_m)_y}{p(d/dp)(a-\beta)}\,\epsilon^{pt}. \tag{88}$$

The values of $p$ being the roots of $a=\beta$, over which the summation ranges, we see that either $a$ or $\beta$ may be eliminated from the numerator. The interchange of $x$ and $y$ makes no difference. Therefore the formula for $V_2$, on the right side of the source at $y$ is just the same as for $V_1$ as far as the summation goes. It can only differ in the expression of the steady part $V_0$.

In passing, it may be remarked that cases may arise in which there is no tending to a steady state. For instance, if the above refers to a circuit consisting of a pair of parallel wires, and the insulation is quite perfect intermediately and terminally, then the effect of $h$ accumulates incessantly, and $V_1$ rises to infinity. The outside term then contains $t$. But such exceptional cases need not delay us here, but can be treated when they arise. At present assume that there is a steady state tended to. There must be one when the source is impulsive, and there is waste of energy in some part (no matter how limited) of the connected system, and there must be one with a steady source unless there is perfect insulation in the way mentioned.

Now in (88) the J and G functions concerned have $sx$ for argument, and the values of $s$ are settled by the determinantal equation. Also $s^2$ is a function of $p$, and so is Z. The further development therefore rests upon the nature of Y and Z in the original circuital equations, for we naturally want to have the result entirely in terms of $s$. If $Z=R$, and $Y=Sp$, we have diffusion, with one value of $p$ for one of $s^2$. Then

$$s^2=-RSp,\quad\text{and}\quad\frac{d}{dp}=-\frac{RS}{2s}\frac{d}{ds}. \tag{89}$$

This brings us to

$$V_1=V_0-\sum\frac{\pi Qs}{S(xy)^m}\,\frac{(J_m-aG_m)_x(J_m-\beta G_m)_y}{(d/ds)(a-\beta)}\,\epsilon^{pt}, \tag{90}$$

where the value of $p$ in the time function is $-s^2/RS$.

If $a=0$, which occurs naturally when $n$ is 1 or more, the last reduces to

$$V_1=V_0+\sum\frac{\pi Qs}{S(xy)^m}\,\frac{J_{mx}J_{my}}{d\beta/ds}\,\epsilon^{pt}, \tag{91}$$

where $\beta=0$ finds the values of $s^2$ and $p$. If the potential is constrained to be zero at $l$, then $B'=0$ in $\beta$, making $J_{ml}=0$ be the determinantal equation. Also $V_0=0$ now. So

$$V_1=\sum\frac{\pi Qs}{Sl(xy)^m}\,\frac{J_{mx}J_{my}G_{ml}}{J'_{ml}}\,\epsilon^{pt}=\sum\frac{2Q}{Sl^2(xy)^m}\,\frac{J_{mx}J_{my}}{(J'_{ml})^2}\,\epsilon^{pt}, \tag{92}$$

Digitized by Google

if the accent denotes differentiation to the argument $sl$. The second form is derived by the conjugate property

$$J_m G'_m - J'_m G_m = -\frac{2}{\pi sl}, \qquad (93)$$

remembering that $J_{ml}=0$. Equation (92) expands an arbitrary form of $x$ to suit the conditions stated. Put $Q=Sy^n v dy$, and integrate with respect to $y$ from 0 to $l$. The result is the V arising from the initial distribution of potential $v$. This also applies when $n$ is smaller, down to just over $-1$, provided $Z_0=\infty$ is imposed terminally.

But if $n$ is $-1$ or less, the solution takes a different form, as before explained. We get, by (57),

$$V_1 = -\frac{\frac{1}{2}\pi R p Q}{(xy)^m}\frac{J_{-mx}(J_m-\beta G_m)_y}{(J_{-m}+B'J_{m+1})_e}(G_m - B'G_{m+1})_e, \qquad (94)$$

with any $Z_1$. So $Z_1=0$, making $B'=0$, makes

$$V_1 = -\frac{\frac{1}{2}\pi R p Q}{(xy)^m}\frac{J_{-mx}}{J_{-ml}}(J_m-\beta G_m)_y G_{ml}, \qquad (95)$$

where $\beta$ is $J_{ml}/G_{ml}$, which makes $V_2=0$ at $l$, $V_2$ being got by interchanging $x$, $y$. The last expands to

$$V_1 = -\Sigma\frac{\pi Q s}{(xy)^m S l}\frac{J_{ml}J_{-my}J_{-mx}}{J'_{-ml}\sin m\pi}\epsilon^{pt}, \qquad (96)$$

subject to $J_{-ml}=0$. The cases in which $m$ is integral had better be kept in terms of $J_m$ and $G_m$. The connection is

$$J_{-m} = J_m\cos m\pi + G_m \sin m\pi, \qquad (97)$$

A companion formula is

$$G_{-m} = G_m\cos m\pi - J_m\sin m\pi. \qquad (98)$$

[See equations (66), (67), (70), (71). But for $\frac{1}{2}m\pi$ in them write $-\frac{1}{2}m\pi$. Also, in (59), $\rho-\sigma$ should be $(\rho-\sigma)\sin m\pi$.]

Equation (96) does not look right. But we have the conjugate property,

$$J_m J_{-m-1} + J_{-m}J_{m+1} = -\frac{2}{\pi sl}\sin m\pi = -J_{-m}J'_m + J_m J'_{-m}, \qquad (99)$$

which may be derived from (29). So, since $J_{-ml}=0$ at present, $J_{ml}$ may be eliminated from (96). This brings it to

$$V_1 = \Sigma\frac{2Q}{Sl^2(xy)^m}\frac{J_{-mx}J_{-my}}{(J'_{-ml})^2}\epsilon^{pt}; \qquad (100)$$

that is, the same form as (92), except in the reversal of the sign of $m$ in the J functions. It is valid when $m$ is $-1$ or less, but the range may be extended up to just under $m=0$ by a terminal restraint making $V_1=0$ at the origin.

§ 348. In the more general case in which R, L, K, S, are all finite, and

$$q^2 = -s^2 = (R+Lp)(K+Sp), \qquad (101)$$

there are two $p$'s for every single $s^2$; thus,

$$p = -j\pm k,\quad j=\tfrac{1}{2}\left(\frac{R}{L}+\frac{K}{S}\right),\quad k=\left\{\tfrac{1}{4}\left(\frac{R}{L}+\frac{K}{S}\right)^2-\frac{RK+s^2}{LS}\right\}^{\frac{1}{2}}, \qquad (102)$$

$$\frac{dq^2}{dp} = -\frac{ds^2}{dp} = S(R+Lp)+L(K+Sp) = \pm 2LSk. \qquad (103)$$

The sum of the two time functions of the form $Z\epsilon^{pt}/(dq^2/dp)$, got by using the above two values of $p$, is therefore

$$\frac{1}{S}\epsilon^{-jt}\left\{\cosh kt + \frac{R/2L - K/2S}{k}\sinh kt\right\} = \frac{\phi(t)}{S}. \qquad (104)$$

To show the application, take the simple case of the potential constrained to vanish both at $\lambda$ and $l$. Then in (90) $V_0=0$, and

$$\frac{d}{ds}(\alpha-\beta) = \frac{d}{ds}\left(\frac{J_{m\lambda}}{G_{m\lambda}}-\frac{J_{ml}}{G_{ml}}\right) = \frac{2}{\pi s}\left(\frac{1}{G^2_{m\lambda}}-\frac{1}{G^2_{ml}}\right), \qquad (105)$$

by using the conjugate property (93), with argument $s\lambda$ or $sl$, as the case may be, and remembering that $\alpha=\beta$.

Therefore (90) takes the special form

$$V_1 = \Sigma\frac{\pi^2 s^2 Q}{2S(xy)^m}\frac{(J_{mx}-\alpha G_{mx})(J_{my}-\alpha G_{my})}{(G_{ml})^{-2}-(G_{m\lambda})^{-2}}\phi(t), \qquad (106)$$

where $\alpha$ is $J_{m\lambda}/G_{m\lambda}$, and $\phi(t)$ is the time function in (104). Its value is 1 when $t=0$, so we can expand any initial state U of potential by (106), by putting $Q=Sy^n U dy$, and integrating.

§ 349. The inclusion of the self-induction in the last makes the magnetic energy operative. The specification of the initial state is therefore incomplete if the potential alone is given. We require to know the initial current as well. Instead of the above $h$, let the source at $y$ be $e$, producing a jump in the potential, thus, $e=V_2-V_1$ at $y$, but with continuity of current, or $C_2=C_1$. To find the result, we need not go through the work in detail, but generalise the former result when the zeroth Bessel function was concerned, § 330. We shall now have

$$V_1 = \tfrac{1}{4}\pi q e\frac{y^{m+1}}{x^m}\frac{(H_m+\alpha K_m)_x(H_{m+1}-bK_{m+1})_y}{b-a}, \qquad (107)$$

$$V_2 = \tfrac{1}{4}\pi q e\frac{y^{m+1}}{x^m}\frac{(H_m+bK_m)_x(H_{m+1}-\alpha K_{m+1})_y}{b-a}; \qquad (108)$$

$V_1$ being on the left, $V_2$ on the right of $y$. We turn $V_1$ to $V_2$ not by interchanging $x$ and $y$, but by interchanging $a$ and $b$ and negativing the result.

The operation $-x^n Z^{-1}(d/dx)$ finds the current. So

$$C_1 = -\tfrac{1}{4}\pi q e\frac{(xy)^{m+1}}{Z(b-a)}(H_{m+1}-\alpha K_{m+1})_x(H_{m+1}-bK_{m+1})_y, \qquad (109)$$

and now $C_2$ is got by interchanging $x$ and $y$.

It is easy to test that these satisfy the conditions at $y$ and terminally, $a$ and $b$ being the same as before, by the conjugate property

$$H_m K_{m+1} + K_m H_{m+1} = \frac{4}{\pi qy} = K_m H'_m - H_m K'_m, \qquad (110)$$

the argument being $qy$, and the accent denoting differentiation to it.

Similarly, to find the solution in terms of $J_m$ and $G_m$, we may derive the results from the last, putting H, K in terms of J and G; but this is tedious, and the results are easily got independently. Thus,

$$V_1 = -\tfrac{1}{2}\pi s e\frac{y^{m+1}}{x^m}\frac{(J_m-\alpha G_m)_x(J_{m+1}-\beta G_{m+1})_y}{\alpha-\beta}, \qquad (111)$$

$$V_2 = -\tfrac{1}{2}\pi s e\frac{y^{m+1}}{x^m}\frac{(J_m-\beta G_m)_y(J_{m+1}-\alpha G_{m+1})_x}{\alpha-\beta}, \qquad (112)$$

show V due to $e$ at $y$. The current on the left of $y$ is

$$C_1 = -\frac{s\pi e}{2Z}(xy)^{m+1}\frac{(J_{m+1}-\alpha G_{m+1})_x(J_{m+1}-\beta G_{m+1})_y}{\alpha\quad\beta}, \qquad (113)$$

and interchanging $x$ and $y$ produces $C_2$. In deriving this we use

$$\frac{1}{s}\frac{d}{dx}\frac{J_m}{x^m} = -\frac{J_{m+1}}{x^m},\qquad \frac{1}{s}\frac{d}{dx}\frac{G_m}{x^m} = -\frac{G_{m+1}}{x^m}, \qquad (114)$$

the argument being $sx$. The continuity in C at $y$ is obvious. The discontinuity in V is easily tested, for we get

$$V_2 - V_1 = \tfrac{1}{2}\pi s y e(J_m G_{m+1} - G_m J_{m+1}) = e. \qquad (115)$$

Since $\alpha$, $\beta$ are as before, the same limitations mentioned apply when $\lambda=0$.

The development in Bessel series is similar. For an initial state of current, let $e$ be impulsive, say $e=p\mathrm{P}$, when P is the momentum generated, as explained in § 327.

Then we get

$$V_1 = -\Sigma\pi s^2 \mathrm{P}\frac{y^{m+1}}{x^m}\frac{(J_m-\alpha G_m)_x(J_{m+1}-\beta G_{m+1})_y}{\frac{ds^2}{dp}\frac{d}{ds}(\alpha-\beta)}\epsilon^{pt} \qquad (116)$$

Here we see that if the potential is made to vanish terminally, and $s^2$ is as in the last section, making two $p$'s to one $s^2$, the two time functions to be added are not the same as before The time function is now $\epsilon^{pt}\div(ds^2/dp)$. The sum of the two is $-(\mathrm{LS}k)^{-1}\epsilon^{-jt}\sinh kt$. So, using this, and (103) and (105) again, we convert (116) to

$$V_1 = \Sigma\tfrac{1}{2}\pi^2 s^3\frac{\mathrm{P}}{\mathrm{LS}k}\frac{y^{m+1}}{x^m}\frac{(J_m-\alpha G_m)_x(J_{m+1}-\alpha G_{m+1})_y}{(G_{m\lambda})^{-2}-(G_{ml})^{-2}}\epsilon^{-jt}\sinh kt, \qquad (117)$$

showing the potential due to the initial momentum P at $y$. Put $\mathrm{P}=Ly^{-n}c\,dy$, and integrate from $\lambda$ to $l$ to show the potential due to the initially given state $c$ of current.

In finding the current due to the initial current, say by the operational solution (113), the presence of Z in the denominator should not be overlooked. Its vanishing introduces another term depending upon $p=-\mathrm{R}/\mathrm{L}$. The interpretation is that if the initial state is $c=$ constant, and we have also

Digitized by Google

$V=0$ imposed terminally, the result is a current $ce^{-Rt/L}$ at time $t$.

The case of terminal resistances is also easily managed, and the same may be said of other terminal arrangements so far as formulæ go, provided we choose them so that the energy is either all electric or all magnetic, which will produce real values of $s^2$. But beyond that, with complex values of $s^2$, and terminal energy concerned, the transformations are troublesome. The work will certainly not be undertaken here, for the sufficient reason of want of space, if there were no other. We have done for the present with normal expansions, and now turn over a new leaf.

*(To be continued.)*

## INSTITUTION OF ELECTRICAL ENGINEERS.

The following are the alterations in the Articles of Association of the Institution, which it is proposed to consider at the Special General Meeting of Members only, called for 4 p.m. this afternoon, at the offices of the Institution :—

| Proposed Alterations. | Old Rules. |
|---|---|
| By striking out the word "twelve" in the second* line of the 36th Article, and substituting the word "fifteen." | 36. The Officers of the Institution shall be a President, four Vice-Presidents, twelve ordinary Members of Council, three Associate Members of Council, two Auditors of Accounts, an Honorary Treasurer, an Honorary Solicitor, an Editor of the Publications of the Institution, a Secretary, and a Librarian. |
| By striking out the word "twelve" in the third line of the 38th Article, and substituting the word "fifteen." | 38. The Council shall consist of the President, all Past-Presidents (including Past-Presidents of "the exi-ting Society"), four Vice-Presidents, twelve Members, three Associates, the Honorary Treasurer, and all these (except the three Associates) shall be chosen from the class of Members. |
| By striking out the 40th Article, and substituting the following Article :— | |
| 40. The following Members of Council, namely—the President, one Vice-President, the Honorary Treasurer, five Members, one Associate—shall be elected annually by ballot. They shall retire annually, and, save as hereinafter provided, be immediately eligible for re-election. Provided that no President, Vice-President, Member of Council, or Associate Member of Council shall hold office in the same capacity for more than three years in succession. | 40. The President, Vice-Presidents, Auditors and Treasurer shall be elected annually by ballot, and, with the exception of the President, shall be immediately eligible for re-election; but the President shall be ineligible for re-election to that office during the following year. |
| By striking out the 41st Article, and substituting the following Article :— | |
| 41. The Auditors shall be elected annually by ballot, but shall be eligible for re-election on the expiration of their year of office. | 41. Three Members of the Council and the three Associate Members shall retire annually, and be ineligible for re-election during the following year. |
| By the addition at the end of the 42nd Article of the following words :— | |
| But the Member so chosen shall retain his office so long only as the vacating Member of Council would have retained the same if no vacancy had occurred. | 42. Casual vacancies in the Council during the year may be filled up by the Council and announced at the next meeting of the Institution. |
| By striking out all words after "Council" in the 7th line of the 43rd Article to the end of that Article, and substituting the following words :— | |
| At an Ordinary General Meeting, held not less than twenty-eight days before the Annual General Meeting, the Chairman shall announce the candidates so nominated. Any two Members, supported by eight other Members, may thereupon nominate in writing any duly qualified person to fill any vacancy by forwarding such nomination, together with the written consent of such person to accept office if elected, to the Secretary within seven days after such meeting. Thereupon a ballot list, containing the names of all persons duly nominated to fill the vacancies on the Council, stating which persons are nominated by the Council, and giving the names of the two Members by whom every other person is nominated, shall be forwarded to the Members and Associates of the Institution not less than seven days before the Annual General Meeting; and each Member or Associate shall be at liberty to make a selection from such list, provided the number of names so selected shall not exceed in any case the number requisite to fill the vacancies. Ballot papers shall be so marked and recorded as may be from time to time determined by the Council. | 43. The Council shall, previous to the Annual General Meeting in each year, prepare a list of members whom they propose as suitable for the offices of President, Vice-Presidents, and Treasurer for the ensuing year. The list shall also contain the names of a sufficient number of Members and Associates to fill the vacancies in the Council, and whom the Council nominate as fitted to become Members of the Council.* A copy of such list shall be forwarded to the Members and Associates of the Institution not less than seven days before the Annual General Meeting, and each Member shall be at liberty to make a selection from the list, or to substitute the name or names of any duly qualified persons for each respective office, but the number of names so selected or substituted must not in any case exceed the number requisite to fill the vacancies. |
| By striking out the words from after the word "quorum" in the third line of the 47th Article down to the word "prescribe" in the fifth line of the same Article, and substituting the following words : | |
| The Council may appoint Committees chosen from their own body, and Committees for special purposes consisting of Members of Council and Members or Associates of the Institution and others, with such powers as the Council may prescribe. | 47. The Council shall meet as often as the business of the Institution may require, and at every meeting five shall constitute a quorum.* The Council may appoint sub-committees chosen from their own body, for special purposes, and with such powers as the Council may prescribe.* In the absence of the President, the senior Vice-President, or, if none be present, the senior Member of Council present shall take the Chair at Council Meetings and at Ordinary Meetings. |
| By striking out the words in the 48th Article from the beginning of the Article to the word "vote" in the third line, and substituting the following words :— | |
| 48. Questions shall be decided at any meeting of the Council by the votes of the Members present, each of whom shall, save as hereinafter mentioned, have one vote: provided that, in the event of there being more than four Past-Presidents at any meeting, the votes of the immediate Past-President and the four senior Past-Presidents present and voting shall alone be counted upon any division; but the Chairman shall have a casting vote. | 48. All questions shall be decided in the Council by the majority of Members present, the acting Chairman having a casting vote*; but at the desire, expressed in writing, of any two Members present, the determination of any subject may be postponed to the succeeding Meeting of the Council, but not beyond that Meeting unless required by a majority of such Meeting. |
| By striking out the 50th Article, and substituting the following Article :— | |
| 50. The financial year of the Institution shall end on the 30th of September in each year; and a statement of the funds of the Institution, and of the receipts and expenditure during such financial year, shall be made, under the direction of the Council, each year, and, after having been verified and signed by the Auditors and approved by the Council, shall be laid before the Annual General Meeting next following. | 50. A statement of the funds of the Institution, and of the receipts and payments during the year, shall be made under the direction of the Council to the close of each year; and, after having been verified and signed by the Auditors, shall be laid before a General Meeting as soon thereafter as may be convenient. |

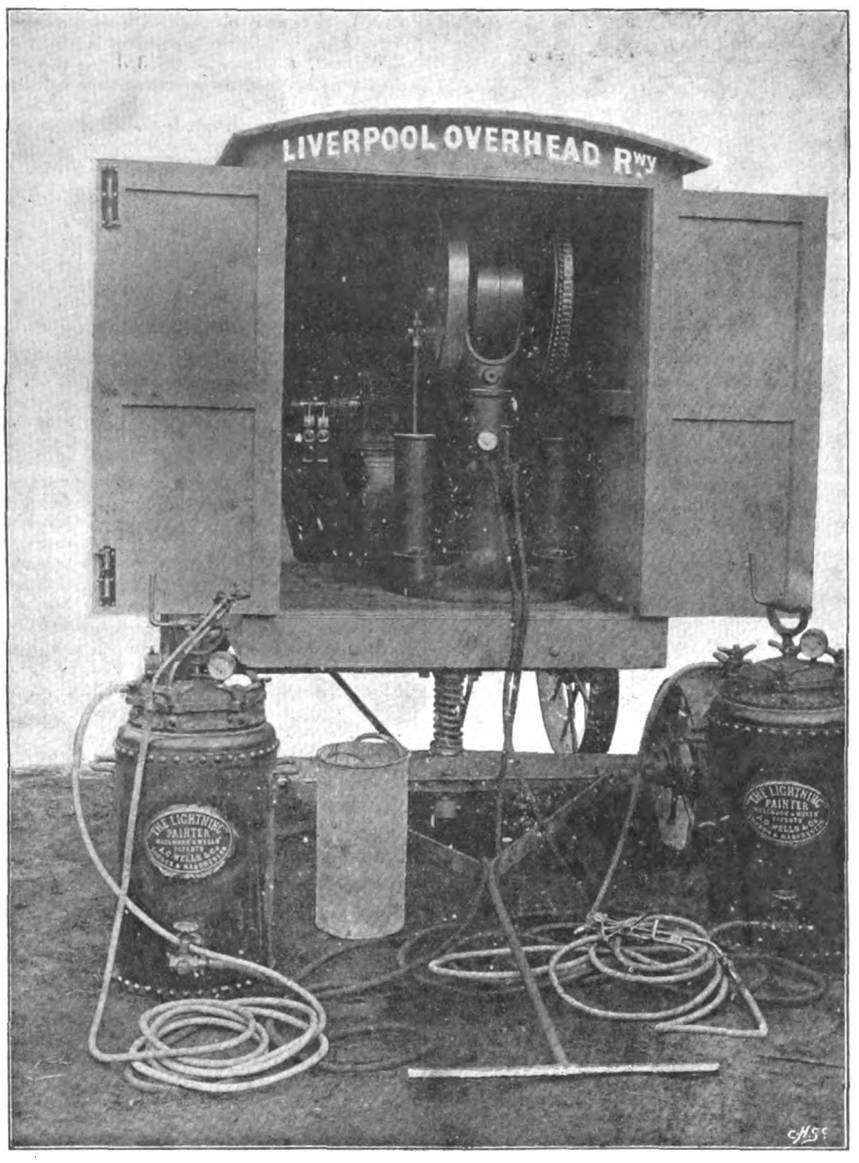
## PORTABLE ELECTRIC PAINTING PLANT FOR THE LIVERPOOL OVERHEAD RAILWAY.

One of the minor but by no means small advantages of an electric system of traction is the existence along the line of power which can be used for driving portable repairing and painting machinery. In any trolley system, or where there is a continuous supply of power by surface conductor rails, as in the City and South London Railway, and the Liverpool Overhead Railway, or again in conduit systems, it is not at all difficult to run an electrically-driven repairing tool by means of power derived by tapping the main power conductor at any convenient point. Thus repairs may be performed more quickly and cheaply than by hand, and heavier repairs than could be done without the aid of motor power can be performed *in situ*.

The latest example of this use of electric power is to be found in a portable painting plant, which has been built by Messrs. A. C. Wells & Co., of London and Manchester, for the Liverpool Overhead Railway. The accompanying illustration has been prepared from a photograph of this plant. Within the car which has been specially built for this painting machine is an electric motor, coupled to the force pump of a Wallwork and Wells spraying painter, together with the paint reservoirs, hoses and auxiliary details. This car can be run on the tramway which lies immediately beneath the overhead track of the electric railway, and by means of flexible cables power can be obtained from the surface conductor on the electric line above. By this means the whole of the extensive girder work on which the electric railway is carried can be covered by the paint spray. Hitherto some 40 hands have been required for painting these girders, and there is little doubt that great economy of time and labour will be effected by the new arrangement. The spraying method, we should mention, is not only used for painting extensive surfaces with a uniform colour, but also, by the aid of stencil plates, it is adopted for painting letters and ornamental work.



Wallwork and Well's Portable Electric Painting Plant.

We understand that for smaller work Messrs. Wells and Co. are making a hand-driven spraying plant, and that their method of spraying the paint, instead of laying it on with a brush, effects considerable economy in the quantity of paint used. Such plants, even when of very small size, if fitted with electric motors, now that power for driving motors is so readily available in large towns, ought to find very general use. They would add one fresh item to the central station engineer's chief delight—a good day load. Though continuous current might be considered preferable, there would be no difficulty in using single-phase alternating currents for this work, as the motors could easily be started by hand.

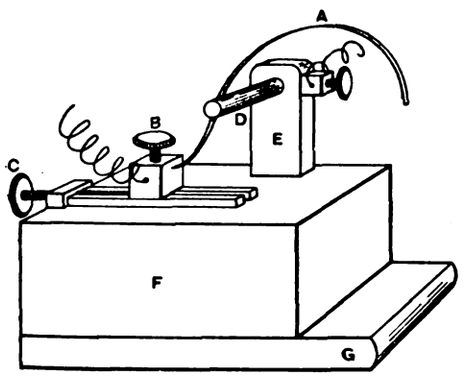
## AN ELECTRICAL TREVELYAN ROCKER.

BY T. A. VAUGHTON.

The following account of what appears to be a new electrical phenomenon which I have been investigating will probably be of interest to the readers of *The Electrician*. In making these investigations I have used an apparatus, of which the accompanying illustration shows the general form, which I have manufactured in the following manner. A piece of watchspring, A, curved into the shape shown, is fixed into the terminal B. This terminal moves along a slide and carries the spring with it, and by means of the screw C the pressure of the spring against the metallic rod D is regulated. This rod is supported by a wooden support, E, and the whole is fixed on to the top of a wooden sounding box, F, which has a projecting piece, G, by means of which it may be clamped down to the bench when in use. On regulating the pressure with which the spring presses against the rod, and the position on the spring of the point of contact, a point will be found on which the spring, when pulled on one side and released suddenly, will vibrate freely in a transverse direction. If, while the spring is thus vibrating, an electric current of a definite strength be passed through the bar and down the spring, the vibrations will be maintained and a musical note will be given out, the pitch of which depends on the length of the free end of the spring. The temperature of the spring and rod gradually rises until a point is reached at which the vibrations cease.



If the apparatus is immersed in water or alcohol just deep enough to cover the point of contact between the spring and rod, the vibrations take place as before, but the sound emitted is weaker. By placing a small split bullet in various positions on the free end of the spring the rate of vibration may be varied and the amplitude increased, and by fixing a small concave mirror on to the spring and reflecting a spot of light from it on to a screen the vibrations may be magnified and observed.

When it is vibrating in water or alcohol the temperature of the liquid rises rather more rapidly than when it is at rest, with the same current passing through it. If the liquid be gradually heated while the vibrations are proceeding, the vibrations gradually weakened, but are not stopped.

The steel spring may be replaced by one of platinum or German silver, but in these cases the vibrations are more feeble. Rods of almost any hard metal may be used, but steel gives the best results, and is followed by iron, German silver, platinum, brass, gas carbon, aluminium and nine-carat gold, in the order named. I have not been able to obtain any sustained vibration with rods of copper, silver, tin and lead, although even with these metals the dying away of the vibration appears to be considerably retarded by the passing of the current. No visible sparking takes place, and there seems to be no interruption of the current.

These phenomena appear to be the effects of the heat generated at the point of contact, although the fact of their taking place under water would at first sight seem to negative this assumption. The apparatus appears to be a sort of electrical Trevelyan rocker.

I have not been able to obtain any results with springs of good conducting metals such as gold, silver and copper, with any current I have used. The rise of temperature at the point of contact does not appear to be enough to give the necessary impulse, and being such good thermal conductors also, the heat is diffused through the mass of the metal more quickly. I have tried springs of various widths from 1mm. up to 7mm., those of about 5mm. being the most easily managed.

There visible to be two or three positions on each spring where the contact may be made and the vibration obtained, the positions between these points not giving them. In these experiments I have used from one to six Bunsen quart cells, coupled in various ways, depending on the size of the spring and its conducting power.

## THE COST OF PRODUCTION OF CALCIUM CARBIDE.

A noteworthy article has appeared in an American publication, the *Progressive Age*, embodying a report by Prof. Houston and Messrs. Kennelly and Kinnicutt, on the cost of production of calcium carbide by the Willson process as worked at Spray, North Carolina. Of the gentlemen named, the first two are well-known electricians, and the last is a recognised chemist, so that the "Commission" constituted by them was competent to decide, as far as data were obtainable, the vexed question of the cost per ton of the raw material for acetylene manufactured on an industrial scale. The Commission was instituted and its cost was borne by the *Progressive Age*, which is entitled to full acknowledgment of its enterprise, and of the successful issue to which that enterprise has been brought. It may be noted that the dubious subject of patent rights for the production of calcium carbide, has also been investigated, but that the present time is not deemed propitious for a definite pronouncement. Further, that the report is presented without comment, and readers on this as on that side of the Atlantic are free to draw their own deductions from the facts and figures supplied.

The plant used at Spray consists of a turbine of about 300 H.P., coupled to alternators which deliver current at 1,000 volts to transformers whereby the pressure is reduced to 100 volts at the furnace terminals. There are two furnaces, each having a floor space of 3ft. by 2ft. 6in., the base being formed of an iron plate protected by a carbon plate 8in. thick. The upper electrode of each furnace is a built-up carbon block 12in. by 8in. in cross-section and 3ft. in length, which can be raised and lowered at will; this electrode is stated to be consumed at the rate of about $\frac{1}{15}$th of an inch per working hour. In making a run, a mixture of coke and lime, containing about 52 per cent. of Ca O and 37 per cent. of C (the balance consisting of moisture and impurities), is used as the charge, and is introduced into the furnace little by little, after the previous establishment of an arc between the upper electrode and a few shovelfuls of the mixture constituting the initial charge. The arc is about 3in. long, and as the calcium carbide is formed by its action, the upper electrode is raised and fresh portions of the mixture added until the furnace is filled to its full height. A mass of crude carbide, of rectangular section and tapering towards the top, is obtained; only about 25 to 50 per cent. of the charge is converted into calcium carbide.

Two complete runs were made, all due care being taken in weighing, sampling, and analysing the charge and the product, and in measuring the electrical energy actually supplied to the furnace. Working with a charge of about 2,000lb. (1 short ton), an output of about 200lb. of calcium carbide was obtained, yielding 80 to 85 per cent. of the calculated quantity of acetylene. The total electrical energy supplied to the furnace was 432 and 386 kilowatt-hours in the two cases, or for the first run of 3 hours, 193·1 H.P., and for the second run of 2 hours 40 minutes, 195·3 H.P. The cost of the carbide made, reckoning the price of power at the turbine shaft at $5 per horse-power year, and that at the furnace terminals at $5·98 per year, taking the cost of the plant at $12,000, and of labour at $11 per day, the value of the carbon of the upper electrode at 6 cents per lb., of the coke at $4·55 per ton, and of the lime at $6·3 per ton, together with

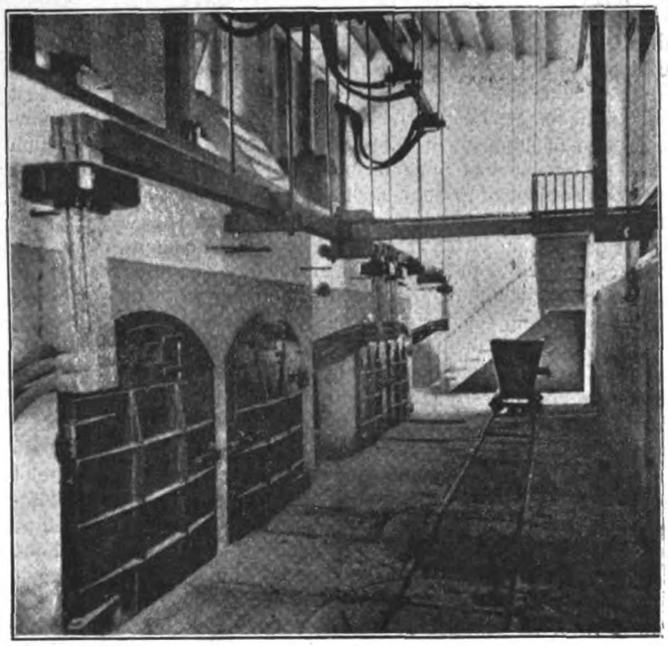
Digitized by Google

fair allowance for depreciation and repairs, is $32·767 for per ton of 2,000 lb. of "gross carbide," *i.e.*, carbide mixed with about 5 per cent. of slag. This corresponds approximately with £7. 4s. per ton of 2,240lb. of a carbide giving about 78 per cent. of the theoretical yield of acetylene.

It will be noted that while the price taken for power is low, the cost of raw material is high, and that the latter item constitutes nearly one-half the total expenditure, whence it follows that places less favourably situated than Spray for obtaining cheap power may nevertheless produce calcium carbide at an equally low rate, by virtue of the smaller expenditure necessary for raw materials.

## CALCIUM CARBIDE PLANT AT NIAGARA FALLS.

The accompanying illustration is prepared from a photograph of the battery of four furnaces for the manufacture of calcium carbide, recently erected by the Acetylene Light, Heat and Power Company, at their works at Niagara Falls. A descriptive account of this electro-chemical factory was published in our issue of April 17, 1896. The factory is supplied with electric power by the Niagara Falls Power



Ca'cium Carbide Furnaces of the Acetylene Light, Heat and Power Company's Works at Niagara Falls.

Company, and each of the four furnaces now erected is designed to consume about 500 H.P., and to manufacture about two and a-half tons of calcium carbide *per diem*. The works have only recently been put into regular operation, and we understand that the inaugural ceremony was a great success, calcium carbide of very satisfactory quality being turned out. It is stated that from the data thus far obtained it is anticipated by the Company that they will be able to manufacture calcium carbide at 23 dollars per ton, in which connection we would refer our readers to the immediately preceding article, where some estimates of the cost of production are summarised.

## EXPERIMENTAL TESTS ON THE INFLUENCE OF THE SHAPE OF THE APPLIED POTENTIAL DIFFERENCE WAVE ON THE IRON LOSSES OF TRANSFORMERS.*

Speakers who have returned their proofs revised are denoted by an asterisk.

DISCUSSION.

*Prof. FLEMING said that as the authors had made some reference to opinions expressed by him at one time and another, perhaps it might be desirable that he should make a few remarks on the Paper, if it were only to correct some erroneous opinions attributed to him. He thought that the authors had not done quite sufficient justice to the work of Dr. Rössler on the subject. A very full and elaborate account of that work was published some six or twelve months ago, in which Dr. Rössler described the investigations he made with machines giving E.M.F. curves in different forms, in order to settle some of those points which had been dealt with in the authors' Paper. Practically he thought Dr. Rössler really covered the whole of the conclusions which the authors had arrived at. Dr. Rössler pointed out most distinctly that the question of the hysteresis loss in transformers when worked off alternators giving different E.M.F. curves really depended upon the ratio between the R.M.S. value and the E.M.F. curve and the true mean value. That was really implied in the conclusions that were arrived at by the authors. The paragraph in which they summed up the whole of their conclusions, pointing out that it depended upon the area of the applied P.D. curve, was really only another way of saying the same thing. He had found it convenient to define a term called the "form factor," which was really the reciprocal of the quantity used by Dr. Rössler, and to define the form factor as the ratio between the true mean value of the P.D. curve and the R.M.S. value. They were all aware of the fact a long time ago that the form of the curve had a great deal to do with the power loss in transformers, and that, broadly speaking, the curve with the peaked or pointed form gave a less loss than those which had the more rounded or square form with the same R.M.S. value. The authors seemed to imply in their Paper that they had the idea at one time that the sine curve gave the greatest loss. He had no intention of implying that notion, for he knew very well that it did not. It was merely the sentence of a letter written to *The Electrician* under the circumstances of the controversy then going on in which some writers had suggested that machines giving sine curves gave less loss, and he pointed out that experiments showed that that was not the case. The authors seemed inclined to minimise the value of experiments made with actual machines. They said at the end of their Paper, "We were anxious, however, to experiment on the waves not actually met with in practice, since our aim was not so much to find out which alternator now on the market was the best, but rather to give some information, if possible, which might be a guide in the future design of alternators for use on transformers." The word "best" was a very large word to use; most people would be prepared to admit that there was no best alternator outside the manufacturers' catalogues, but that each one had certain advantages of its own. In the selection of machinery for particular purposes they had to be guided by the end in view, and in order to improve any existing apparatus the first step was to know what the present forms were able to achieve. Therefore the obvious direct process was to investigate with some care the behaviour of well-known and different types of alternators in that respect. That was what Dr. Rössler did. He took two machines of a well-known form—Ganz and Wechsler machines—and analysed their performances very carefully. His (Prof. Fleming's) own attention was directed chiefly to the Mordey, Thomson-Houston and Ferranti machine for the same purpose, because machines that had had so much experience and brains put into them had not been designed without a great deal of thought, and therefore any attempt to improve them must be preceded by a very careful study of what they were able to do. With regard to improving any piece of machinery, all good design was really a compromise, and they could not have all they wanted; they must be prepared to give up some things in order to get others, and the adaptation of the different portions of the design one to another must be governed by the end in view. So it was with regard to the problem before them. It had been well understood for a long time that the peaked form of the E.M.F. curve gave the least loss, or a smaller loss, on the transformer than did a curve with a more rounded form. Any manufacturer would be prepared to give a machine with a curve as sharp as a serpent's tooth, but that would be accompanied with certain other great disadvantages, because it would be well understood that the secondary drop on the transformers was increased thereby, and also that with the increase of the maximum value of the curve a greater strain was brought upon the insulation. Of two sets of machines on one of the London supply stations, one of the machines gave 1,000 volts more maximum pressure than another working at the same R.M.S value. Although the station voltmeter showed the same value on the machines, yet there was an absolute maximum of 1,000 volts more in one than in the other under certain conditions; there would be no total advantage gained by purchasing a diminution in the core loss by a greatly increased secondary drop, and at the same time running the risk of breaking down half the cables every time the machine was switched on. From the practical point of view the question of what form should be given to the E.M.F. curve must be governed, not only by the question of the loss of the transformer, but also by the question of the secondary drop, and the insulation difficulties that occurred. His own feeling was that there was not a great deal which could be done in that direction, because of those two conflicting results arising from altering so much the

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

E.M.F. curve. They could give it a little more peaked form, and in that way diminish the hysteresis loss of the transformer; but at the same time they were bringing themselves into other difficulties. The machine which the authors had designed gave them the power of arbitrarily varying the form to a much greater degree than was found in actual practice. Although it was a common idea that an alternating-current machine had a particular wave form attached to it, that was not the case at all; it depended very largely on the nature of the load the machine was carrying, and on what the armature reaction in that machine was. But, at any rate, it was known perfectly well that the forms which were likely to be useful in practice would not vary over very wide limits, and, therefore, there was nothing in the mere fact of the discovery that some very unusual or extravagant form of curve would have certain peculiar difficulties in respect of the core loss, because that must be governed by the number of different conditions. Looking at it from the point of view of the station engineer, they had to consider not only the questions involved in the form of the curve, but also the various other qualities which the alternator must possess. His own feeling at the present moment was that there was not a great deal to be done in that direction. Something might be done, but at the same time, as regarded the diminution of losses in transformers, there was a great deal more to be gained by studying the transformer itself and by improving it than there was to be gained by dealing with the form of the E.M.F. curve. A far more important question that presented itself as a very practical matter was the discovery of some means for preventing that increase in the core loss of transformers that went on at that time. The iron could be annealed down to a point at which that loss became a decimal, but the difficulty was to keep it there. With regard to the point that the authors had mentioned as to the possibility of building up the wave form with a few harmonics, there was no question that with regard to forms which were likely to be met with in practice, or which were met with in practice, the first three odd harmonics were quite sufficient to build up that curve. But at the same time it was also perfectly true that the moment they went away from forms which were more or less regular, then that was an insufficient number to give the required synthesis. It would have been an important addition to the Paper if the authors had been able to make some careful quantitative measurement in that respect, having groups of widely different form factors having, of course, the same R.M.S. value for the E.M.F., and then making exact measurements of the hysteresis loss in one and the same transformer worked off those different P.D. curves, and showing whether the form factor was actually proportional to the loss or whether it merely increased with it. In some statements concerning the increase of core loss in transformers some time ago he guarded himself against the expression of opinion that it was precisely proportional to the form factor, because at that time he had no means of actually proving it. That was a point he looked for in the Paper, but he did not find it set out in the manner in which he hoped it would be, and if the authors with the appliances at their command were able to settle that point definitely he thought they would have added to the knowledge on the subject.

*Mr. W. G. RHODES said the subject might be attacked from a slightly theoretical point of view. As the Paper dealt entirely with transformers on open secondary it was permissible to consider the P.D. of the primary terminals to be approximately the same as the back E.M.F. Consequently, if A was the area of the core and N the number of turns on the primary, the P.D. at the primary terminals might be written equal to $A N \frac{d b}{d t}$, where $b$ is the induction at any instant. If the equation were integrated they would obtain the integral of $V\,dt = A N B$, where B was the maximum value of the induction, the limits being taken as explained in the paper by the authors. The integral $\int V\,dt$ was the area of the P.D. curve, and representing that by S, the following equation was obtained, $S = A N B$. They knew, partly from theory and partly from previous experimental work, that the total losses in the transformer, divided into hysteresis losses and eddy currents, were given by

$$k_1 n B^{\alpha} + k_2 (n B)^2,$$

the power $\alpha$ varying from 1·4 to 1·6. They could substitute the value of the maximum induction in terms of the area of the P.D. curve and get for the total iron loss,

$$\frac{k_1 n S^{\alpha}}{A^{\alpha} N^{\alpha}} + \frac{k_2 n^2 S^2}{A^2 N^2},$$

which showed that the total iron losses depended simply upon the area of the P.D. curve. It also showed that it was not strictly proportional to the area; part of it was proportional to the square of the area and part to the area raised to the power $\alpha$ (=1·4 to 1·6). This assumed that the frequency was constant. With regard to the problem of making those losses as small as possible, although one might have to compromise between losses in one way and losses in another way, still it was a matter of practical interest to know how the iron losses could be reduced to a minimum. There might be particular circumstances connected with the machine in which it was advisable that the iron losses should be very small, and it was well to know exactly what to do in order to minimise them. If they had to work at a given virtual P.D. that was to be constant, they would have to make the integral of the square equal to some constant, and at the same time make the integral $V\,dt$ a minimum, or

$$\int V^2\,dt = C,$$

and $\int V\,dt = \text{min.}$

Theory showed that there was no minimum provided they did not limit their maximum P.D. The maximum P.D., of course, was in practice limited according to the special circumstances of any particular case: that would fix the minimum to which they could possibly work, but there was no absolute minimum. They could fix any minimum they liked.

*Mr. S. EVERSHED said that when he read the Paper a day or two ago he rather felt with Dr. Fleming that from the point of view of the designer of alternators there was practically little to be done in the direction indicated by the Paper. It would hardly pay to design machines to give any different wave from those which were now in common use. But while he came to that conclusion he did not see that it detracted in any way from the value of the record of experimental work such as had been brought forward that evening. The whole subject of alternate current machinery had been so involved in mystery and so wrapped up with the sine wave that it was very desirable that experimental work should be done once for all to clear up some of the mysteries. It seemed to him, however, that in dealing with the design of alternating current machinery, they had to think more of the central station engineer; and he would at once ask, "How many Board of Trade units per annum am I going to save if I adopt a more efficient wave?" If they took a station delivering two or three million units per annum, they might fairly say that if the transformers were banked, they would practically have to magnetise all day long the cores of a number of transformers whose total capacity would be possibly four million units per annum. They might by economical working manage to do with less magnetised iron than that, but at the present moment it was quite fair to say that that would at least be the amount. If they took the differences given in the Paper for the different wave forms, the differences in the iron losses, they found that if they were to substitute for the present machines—which might be assumed to be giving sine waves more or less—some of the machines which gave a better form, they might reckon in practice to save 10 per cent. of the present iron loss; that was to say, they might save 10 per cent. of the 2½ per cent. now lost. The 2½ per cent. on 4,000,000 units worked out at exactly 100,000 units, so that it would amount to a saving of 10,000 Board of Trade units per annum. But the 2d. or 3d. per unit which those units cost at the works would not be saved if they were not produced. All that would be saved would be the coal and a little oil and waste and things of that kind. The total saving per unit might be put at 1d., and therefore the whole saving would amount to £42 per annum. He doubted very much if there was any central-station engineer who would think it worth while to change his machinery to save that; and he thought that even if anyone was starting a station he would hardly consider, in choosing his machinery, whether the machine had the most "efficient" form of wave. He thought he would be quite content with the sine wave so long as the machines were otherwise satisfactory. It was very well known that machines giving the "efficient" type of wave mentioned by the authors must have notched armatures, that was, they must have iron pole-pieces going by fixed iron poles, and machines of that type were necessarily subjected to a good deal more vibration than simple core or coreless dynamos. Those were considerations which would be of far more importance than the actual shape of the wave. He thought the authors would agree with him that the shape of the eddy current waves should be exactly the same as that of the P.D. waves. That being so he thought they should look for experimental errors, or arithmetical errors, when they found that the eddy current wave was not the same. He noticed that the authors spoke throughout of the R.M.S. value of current. He did not like that. They had all been so accustomed to speaking of "effective" current and "effective" E.M.F., that he must really enter a little protest against a new phrase.

*Mr. TREMLETT CARTER disagreed with Mr. Evershed who had stated that the form of a wave was not a practical question. He wished that the discussion might be shared partly by American and partly by English engineers, as the Americans are taking a very great interest in this question, both from the theoretical and practical point of view. In fact, it was the practice of American engineers in building so-called sine wave alternators which first turned the attention of electrical engineers in England to the matter. At the present time, in America, where alternate-currents are used for more diverse purposes than they are here, alternator builders are making and advertising alternators, giving very different types of wave form. They will offer a saw-tooth shape of wave for general purposes and a flat-topped wave, curiously enough, for transformer work—just the opposite to that which the authors of this Paper recommend, and have proved is the best for the purpose—and they will offer a simple sine wave alternator practically without harmonics of any sort for very long distance transmission. They contend that for long distance transmission the absence of harmonics diminishes the line drop. He thought, therefore, that this was a very practical question. He also thought that the use of different kinds of waves in transformers should be decided by what the transformer is intended to do. A recent Paper read by Mr. Frith before the Physical Society of London showed that for arc-lighting purposes the arc has the power of modifying the shape of the wave so as to make it a flat-topped wave when it is applied directly to the alternator, but that it has not that power of distorting the wave when it is run off a transformer of a lighting circuit. Consequently, for arc-lighting purposes we ought to consider what type of wave we are going to send into the transformer, and we should use a different type of wave from that which we require if we are going to use transformers for general supply or incandescent lighting. He had not had time to study the Paper thoroughly, and was unable at that early stage to criticise it in detail, but he congratulated the authors both on their development of the subject from the engineering point of view and for the ingenuity with which they had devised apparatus to obtain their results, and to draw the conclusions which were so lucidly brought before the meeting in their Paper.

*The CHAIRMAN (Prof. Ayrton) said that while the authors were engaged on this investigation Dr. Fleming, who had himself made experiments on the subject, stated as his conclusion, that "the iron core loss in any transformer was greatest on that alternator the E.M.F. curve of which most closely approximated to a sine wave." That was published in June last. It was but fair, therefore, for the authors to say, to themselves, "If that is the case, then we may draw a very important con-

Digitized by Google

clusion—if the sine wave be the worst to use let us use a very flat wave." He did not think they had brought that out sufficiently in their Paper. They all knew what Dr. Fleming had told them, that certain dynamos having the same R.M.S. wave of P.D. might have a very much higher maximum which might break down the insulation. Therefore let them use a wave that would not have a high maximum, and they would, according to Dr. Fleming, have an efficient wave. It was as much that as anything else that the authors set themselves to try and solve, to try and find out by experiment, "Is it true that a very flat wave, which is a very safe wave, is also efficient for transformers? If so, it is the very thing to use." That did not, however, turn out to be the case—it was not good to use. It was not a fact that the sine wave stood out as a very bad wave, and that whether they went up or down, whether they had a dangerous or safe wave, they got a more efficient wave. The authors had shown that if they went up they no doubt got danger, but they got much greater efficiency; whereas, if they went down and flattened the wave, they got less efficiency. The sine wave was neither very good nor very bad. He did not think it could be said that the authors had not done full justice to Dr. Rössler's investigations. These investigations were fully acknowledged in the Paper, but to save time the authors had omitted to read their remarks on them. It might be said that if they obtained those results last year, why were they not published at once? He was personally to blame for that, because the authors were desirous of publishing their investigations in *The Electrician* about the middle of last year. Had they followed their own wishes the Paper would have appeared several months ago, and there would have been no question of precedence. He had advised them, not knowing what was being done in other places, to offer the Paper to the Institution of Electrical Engineers. It was impossible to hold the first meeting of the Institution this session because the building was not ready, and then followed a long period devoted to the discussion on house wiring. With reference to the injector, of course in laboratories, when old and young were working together, ideas might come from the older to the younger members, but in the present case the idea of the injector was absolutely the authors' own. He agreed with Dr. Fleming that it was a valuable and economical instrument for enabling one to get any shape of wave. Mr. Taylor had said that condensers were expensive, and it might be thought that the injector only represented a small fraction of the whole cost, and that a large sum must be spent in buying condensers; but it was pointed out in the Paper that the greatest change in the wave was produced by the use of the very smallest capacity. The great value of the arrangement was that it enabled one to make a wave exactly in the way one drew a person's face. They did not have a number of harmonics and wobble about when they wanted to draw the forehead—the forehead was drawn. The same thing applied to the mouth, nose and chin. By combining machines, pulleys and cords, combining a series of harmonics, they might try to get a certain result by wobbling all the time, but that was not the best way, because every part of the wave was influenced by the remainder. He congratulated the authors on the success of their instrument and in their application of it to the examination of the iron losses in transformers.

*Mr. J. MARK BARR, in reply, said that Prof. Ayrton had so very admirably replied to Dr. Fleming's criticism that he felt that there was not much for him to say. The illustration with reference to the drawing of a face as a Fourier function, he thought utterly disposed of the idea of easily combining the harmonics as being better than using the injector. As the authors had said in the Paper, when they have a smooth fundamental, if they wish a piece taken out of it they take it out directly; not destroying that fundamental first, and then dealing anew with a large number of complicated elements. As Prof. Ayrton had pointed out, that was a great advantage. Prof. Ayrton had also very well disposed of other things that Dr. Fleming had said, and he could hardly do more than merely thank him. There was one thing more that he would like to say. The authors had laid no emphasis on the fact that they wished absolutely to avoid trying any wave produced by a dynamo in practice. He simply felt that heretofore when anyone had experimented on the effect of different wave shapes, and, therefore, had used machines in practice, he had been beset with this difficulty and danger, that for the same effective value of volts or R.M.S. value, he did not get much difference in the shapes of the waves or in the area. The authors noticed, among hundreds of people interested in the subject, that the results with different wave forms of practice did not differ much, and therefore a great danger came in when such differences were found. One asks, Are not these differences due less to the variations in wave shapes than to experimental difficulties and errors? So the authors said they would supplement the known tests by experiments made with waves exaggerated. Then, if, as a wave was more and more peaked better results were obtained, and, on the other hand, if, as the waves were made flatter and flatter a higher iron loss was obtained, the published results were correct, and also their results were correct. In order to establish the validity of a law one should take advantage of the relations of the more marked effects, and deal with quantities differing by values as large as can be obtained. He thought he had disposed, then, of one great danger in the statements made at the conclusion of the experiments of Dr. Rossler and others. In every case, especially in one of the theoretical cases, the waves they used did not differ enough in shape, and when they differed enough in shape they did not differ enough in area. That was the great point. Dr. Fleming, in speaking of the injector, said it was wrong to regard a dynamo as having a given wave form attached to it. That was hardly so, because although in a machine with a sine wave, the form of the P.D. changed with the load, it was not a very radical change. The wave form is rather a rigid thing, and with one dynamo it was very hard to get a number of wave shapes differing enough in contour and area for a given effective voltage. One must have some definite method of absolutely cutting a piece out of the wave if one wanted to change it very much.

*Mr. C. P. TAYLOR, in reply, after thanking the speakers for the kind manner in which they had criticised the Paper, said that Dr. Fleming had stated that practically the condition of the effect of the wave form on the iron losses in a transformer was a very small one in the question of central station economy. That might be so, but he thought it must be an advantage to know that condition, and, indeed, all the conditions, more accurately in order to decide how to design a central station, and in order to obtain the maximum efficiency of distribution. He did not agree with Mr. Rhodes that the eddy current losses varied with the square of the maximum induction: he thought it varied with the square of the effective P.D. They considered that their experiments showed that, and, if the eddy currents did act like a secondary, it was evident that it did not depend on the maximum induction at all. It was also shown in Dr. Rössler's Paper that the eddy currents did not depend on the maximum induction, but on the mean value of $\left(\frac{d\,B}{d\,t}\right)^2$—*i.e.*, on the square of the effective P.D.

He regretted that, owing to want of time, he had not mentioned Dr. Rössler's work in reading the paper; they had found it very interesting, and had made several notes on it, which appeared at the end of their communication.

*The CHAIRMAN proposed that they should accord a hearty vote of thanks to the authors for the very interesting communication to which they had listened, and this was carried unanimously.

## NOTES ON SOME AMERICAN ALTERNATING-CURRENT MACHINERY.*

*(Continued from page 22.)*

### Generators and Synchronous Motors.

Although the alternating current and alternating-current systems have opened an extensive and important field of application, and notwithstanding the difficulties which may be surmounted by their employment in the long-distance transmission of power and light, made possible by the use of high potentials, there still remains an important commercial field in which, were it impossible to transform to direct currents, their applications would be considerably reduced, and the development which they have at present attained could not possibly have taken place. The necessity for having direct currents is to be met on every hand, and it is by means of the rotary transformer that this necessity has been supplied.

*Rotary Transformers.*—This very important class of electrical machinery, invented some years ago by Mr. Bradley, permits of the use of alternating-currents transmitted through very long distances and at high potentials, and with a consequent small loss, to be transformed into direct currents at the place of consumption, so that they may be utilised in their various applications, as for street railway propulsion, electrolytic purposes and numerous chemical processes. Any continuous-current machine can be made a rotary transformer of any polyphase type by tapping the armature at the desired number of equidistant points, and connecting these points to independent collector rings. Obviously, the frequency of the alternating currents must be directly proportional to the speed of the machine and the number of pairs of poles. As an instance may be mentioned the Portland and the Lowell transformers, both of which are used for street railway work. They are built for a 550-volt continuous current. Two-phase rotary transformers are employed by the Pittsburg Reduction Company at Niagara Falls. Two-phase currents at a difference of potential of 2,000 volts are generated at the power-house at Niagara and transmitted a short distance to the power-house of the Pittsburg Reduction Company, where the potential is reduced to 110 volts alternating by means of stationary transformers of the air-blast type. This two-phase current supplies the rotary transformer, and the continuous current taken from its commutator side has a potential of $110 \times \sqrt{2} = 105$ volts. These rotary transformers are each of 400 kilowatts capacity, have 20 poles, and run at 150 revolutions per minute; that is, at 25 cycles per second. The Portland three-phase transformers are each of 400 kilowatts capacity, have eight poles, and run at 500 revolutions per minute. Both types are simply continuous-current machines, having their armatures tapped at three equidistant points for the three-phase transformer and at four equidistant points for the two-phase transformer. The ratio between the continuous and the three-phase voltage is $1 : \frac{1}{\sqrt{3}}$, or 1 : 0·577, and between the continuous and the two-phase $1 : \frac{1}{\sqrt{2}}$, or 1 : 0·708.

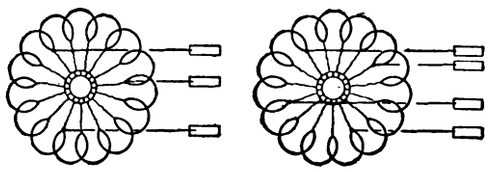
The transformers are made self-exciting. In starting a rotary transformer, or, in fact, any synchronous motor, it has at first no field excitation. The field is thrown on after synchronism is attained, the armature currents furnishing in the meantime sufficient reaction to give the necessary starting torque. Even

* Abstract from the *Electrical World* of New York. We are indebted to our New York contemporary for the blocks illustrating this article, which gives a useful insight into American methods.

Digitized by Google

with the same load, by varying the field excitation, the current received by the synchronous motor or rotary transformer can be greatly varied, since either is capable of producing a leading or lagging current in the lines. A leading current increases the magnetisation of the generator, and tends to demagnetise the transformer, while a lagging current tends to demagnetise the generator and increase the magnetisation of the transformer. If the transformers have sufficient compounding so as to have always a higher counter E.M.F. than the impressed, the current in the line will lead, and consequently increase the magnetisation of the generators. This feature offers a means of compounding the generators with the armature reaction without series-field. Figs. 19 and 20 show how the connections are taken from the armatures of the three-phase and two-phase rotary transformers.

*Alternating-Current Systems.*—Two standard alternating-current systems have been adopted by the General Electric Company, viz.: the three-phase and the monocyclic. It is only in special cases that the two-phase system is employed. The three-phase system is used in places where power is to be transmitted at very high



FIGS. 19 and 20.

potentials and for long distances, and chiefly supplied to motors. One very important advantage of the three-phase system over the single-plase is that the saving in copper is about 25 per cent. All of the standard three-phasers are built for 60 cycles. Generators which are wound for the line potential are preferably used when the line is not long, and then in connection with step-up transformers. The standard three-phasers are at present being wound for 1,150, 2,300, and 3,450 volts. Higher voltage machines are used in special cases. In stepping up or in distributing three-phase power, two or three transformers may be used. If two are used they are connected in series across the mains, so as to have a main at each side of each transformer, as indicated in Fig. 21.

Three transformers ought preferably to be used, so that if one should be damaged by lightning or other cause, the plant need not be shut down, but can be operated on the remaining two.

On the three-phase system, synchronous as well as induction motors can be operated. The synchronous motors are practically always self-starting, but start with moderate torque, and with a current of about two or three times that required at full load. When in synchronism they run at constant speed, being always in

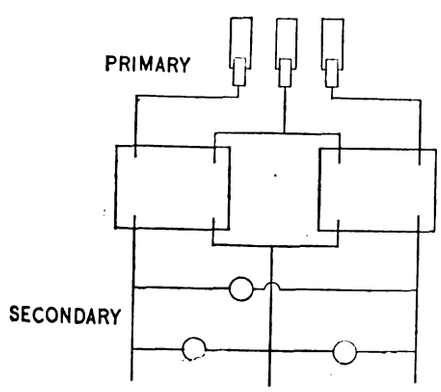


FIG. 21.

perfect synchronism with the generator. They have no idle currents, and consequently do not load up the generators and line unnecessarily. Since the generators and synchronous motors are identical in sizes from 50 kilowatts to 1,000 kilowatts, the standard generators are used as synchronous motors.

*Induction Motors.*—The induction motors start with any desired torque for which they are designed. The standard make have about 50 per cent. greater starting torque than the full load running torque. The current required in starting is the same as that when running with the same torque, consequently if a motor is designed with a 50 per cent. greater starting torque than running torque, the starting current is 50 per cent. greater than the running current. These motors are designed with and without external resistance in the secondary induced member; that is, in the revolving armature. The advantage of this resistance is obvious, since the starting torque, the drop in speed, and efficiency are dependent thereon. If the motor is designed with no special starting resistance, but with such high armature resistance as to give twice the starting torque of the full load running torque, the efficiency will be low and the drop in speed considerable. If the motor be designed with a special resistance in the armature that may be cut out when the motor is running, we have in starting the advantages just mentioned; that is, we have a motor giving any desired starting torque, with the same amount of current corresponding to this torque, and further, a motor that is very efficient and which will show a very small drop in speed when running under variable load. The exciting

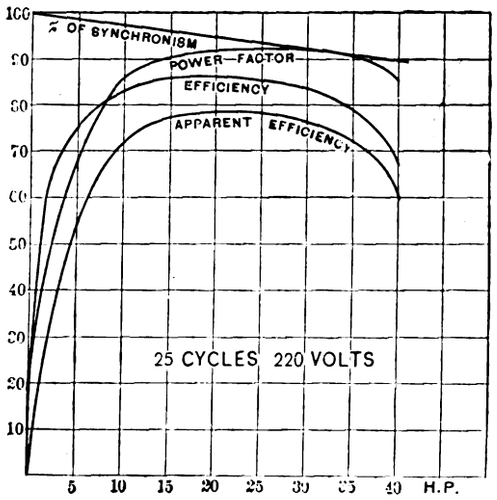

FIG. 22.

current of these motors, that is, the current taken when the motor is running light, is between 25 per cent. and 30 per cent. of the full load current, but since the power factor when running light is very small, as, for instance, from 10 to 15 per cent., this current represents scarcely any power.

The induction motors are designed with an exceedingly simple field and armature winding. The slots are open, so as to have as small self-induction as possible, and the coils, which are machine wound, are put in the slots after being insulated. The great

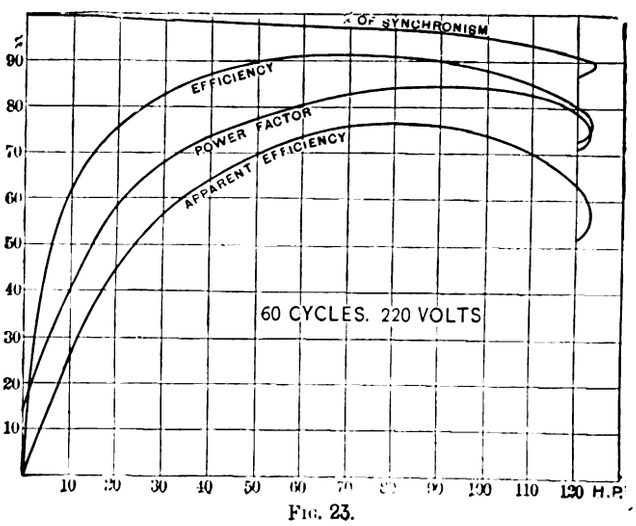

FIG. 23.

advantage in the use of induction motors is the absence of any movable contacts, either in armature or field. Consequently these motors can advantageously be used in places where, due to fire insurance restrictions, no continuous-current motor or alternating-current motor with collector rings would be allowed, on account of the danger due to sparking.

We give in Figs. 22, 23 and 24 complete curves showing the behaviour of some of these motors, the power factor, apparent efficiency and the current input. One of these curves is for a 20-H.P. 25-cycle motor, the other for a 75-H.P. 60-cycle motor, and the third of a 5-H.P. 60-cycle motor.

By looking at the curves of the 25-cycle motor, it will be seen that the maximum efficiency of this motor is 86 per cent., the maximum power factor which is reached rather near to the full load point, 92 per cent., and the maximum apparent efficiency is as high as 78·5 per cent. At full load, that is at 20 H.P., the efficiency is

Digitized by Google

86 per cent., the power factor 91·51 per cent., and the apparent efficiency 78·5 per cent. The power factor running light is extremely low, being only 18 per cent., which shows that a very small part of the current consumed while running light represents energy. The drop in speed at full load is 4·5 per cent. The maximum output of this motor is 40 H.P., or 100 H.P. more than the full load power. The starting torque of this motor is about 150 per cent. greater than the full load torque.

Fig. 23 gives the data concerning the 75-H.P. 60-cycle induction motor. The maximum apparent efficiency of this motor is reached at full load and is as high as 76 per cent. The maximum efficiency is 91 per cent., and the maximum power factor 84 per cent. At full load the power factor is 83 per cent., the efficiency 91 per cent.,

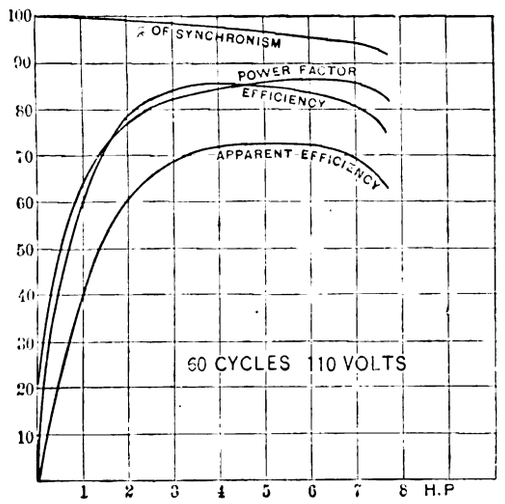

Fig. 24.

and the apparent efficiency, as stated above, 76 per cent. The drop in speed is only 3 per cent. The power factor running light is only 14 per cent. The starting torque of this motor is 80 per cent. more than full load torque.

Fig. 24 gives the data pertaining to a 60-cycle motor. The curves show that this motor for its size is as near perfection as can be expected. At full load the efficiency is as high as 85 per cent., and at three-quarter load as high as 86 per cent. The power factor at full load is 85 per cent. and at 6·6 H.P. a maximum of 86·5 per cent. The apparent efficiency is as high as 72·5 per cent. over a very wide range of power. The starting torque is 60 per cent. greater than the full load torque. The drop in speed at full load 2·5 per cent.

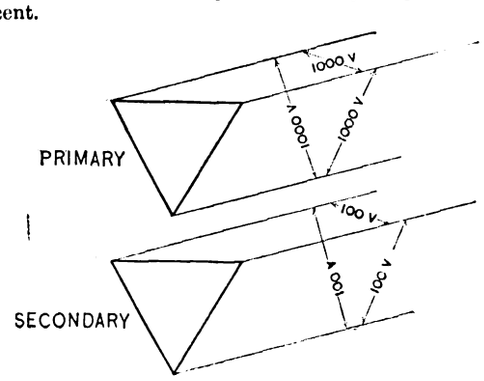

Fig. 25.

The most important features to be considered in an induction motor are the efficiency, power factor, apparent efficiency, the current taken by the motor when running light, the starting current, the starting torque and the variation in speed under a variable load. The efficiency of the motor depends upon the amount of copper and iron used in its construction, upon the current used and the friction loss, since the various losses consist of the $C^2R$ loss, the hysteresis loss and loss due to friction. It is the ratio between the watts utilized by the motor and the watts supplied. The power-factor, which is the ratio between the energy current and total current supplied, depends therefore upon the amount of magnetising current in the motor, and is consequently lower, the larger the length of the air gap, the larger the density in the gap and in the iron, and is expressed as the ratio between the watts input and the total volt-amperes input.

The apparent efficiency is the product of the efficiency and the power factor, and is consequently the ratio between the total output and the total volt-amperes input. The induction motor when running light consumes a certain amount of current, part of which is wattless and part of which represents energy. The wattless current is the current magnetising the motor, so as to produce the same counter E.M.F. as the impressed. The energy current is the current consumed by Foucault currents and hysteresis and the cur-

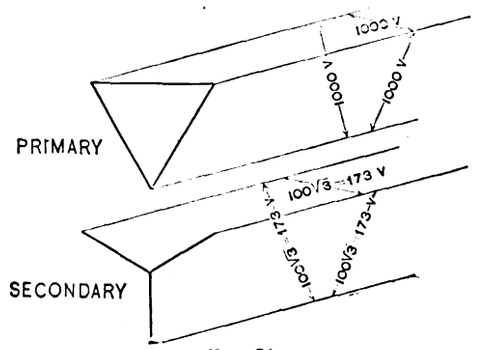

Fig. 26.

rent necessary to drive the motor in its own bearings, that is, the energy current is partly a hysteretic current and partly a current consumed by friction losses.

The magnetising current is 90 deg. behind the E.M.F., and does not represent any energy, consequently, although considerable current is consumed when the motor is running light since most of it is the magnetising current, this current cannot be considered as representing any actual power taken from the generator.

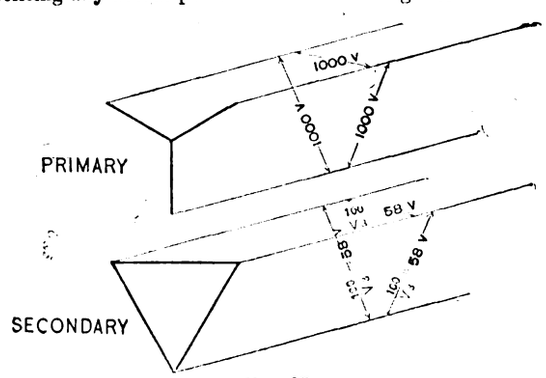

Fig. 27.

*Lights.*—Lights can be operated from the three-phase system, either from a single transformer placed in one leg only, in case the number of lights to be carried is small compared with the total output of the generator, or from all three legs if the amount of lighting to be done is large.

Figs. 25 to 28 show some of the different methods of connecting transformers in the three-phase system in order to obtain different

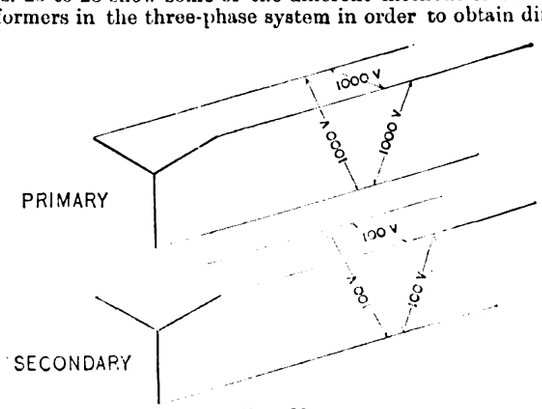

Fig. 28.

voltages. It is found that with the same transformer the potential at the terminals of the secondary may vary considerably, depending upon the connections of the primaries and secondaries. In Fig. 25 with the primaries and secondaries Δ connected, the ratio of transformation of primary and secondary is the same as the ratio of transformation of the transformers, so that for instance, if the transformers have the ratio 10 : 1, and the primary potential between the lines is 1,000 volts, the potential at the secondary

Digitized by Google

between each of the three legs is 100 volts. If the primaries are Δ connected and the secondaries Y connected, as in Fig. 26, the potential between the three secondary lines will be 173 volts, or $100 \times \sqrt{3}$. If the primaries are Y connected and the secondaries Δ connected, (Fig 27) the potential between each of the secondary mains will be $\frac{100}{\sqrt{3}}$ or 58 volts. The most economical system of distributing lights from the three-phase secondaries is by the use of the common connection; that is, by having the secondaries connected in the Y manner. And finally, if the primaries and secondaries are Y connected (Fig 28) the voltages are transformed in the ratio of transformation of the transformers. Each transformer is then subjected to a lower voltage than that of the main, the ratio being $1 : \sqrt{3}$.

*Monocyclic System.*—This system is used where most of the power generated is to be utilized for lighting purposes, since in this system no unbalancing can occur. The monocyclic system takes

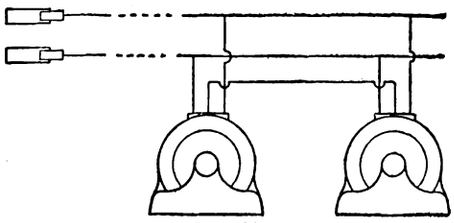

Fig. 29.

a trifle more copper than the straight single-phase system, as the monocyclic mains have to be calculated in the same manner as the single-phase mains and the teaser wire added, but since this system requires but two mains to those places where lights only are located, and the third teaser conductor to places only where motors are to be operated, the question of copper in the line of the monocyclic system can be treated in the same way as in the straight single-phase system. The monocyclic system does, however, not necessarily include the monocyclic generator. Its main feature lies in the establishing of a displaced voltage which is used in starting and running motors. This displaced E.M.F. need not necessarily be derived from the generator, but can be supplied from any part of the system of distribution. Consequently if power is required at great distances from the generator, two mains only are run to those points, and by other means the displaced E.M.F. is established.

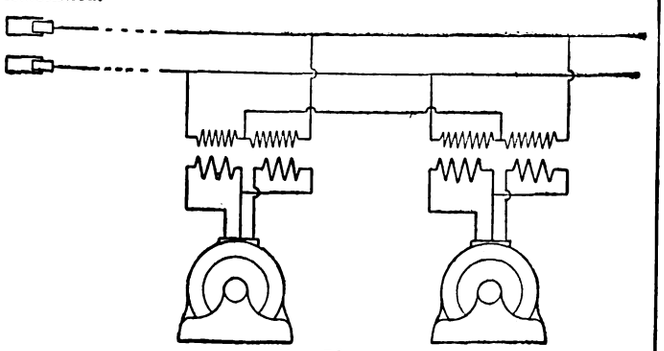

Fig. 30.

This may be accomplished, for instance, by a three-phase induction motor running single-phase. Although this motor is running single-phase, due to the interaction between its impressed and counter E.M.F., it will be found that at the terminals there exist E.M.F.'s of an approximate three-phase relation. One of these E.M.F.'s is that due to the main, the others being due to the resultants of the main and the out-of-phase E.M.F. established by the motor.

If leads are brought from this second terminal of the induction motor to other motors, as shown in Figs. 29 and 30, these motors will not only run up to full speed, but will start practically with any desired torque.

The action between the first motor and the others will be practically the same as if this third phase was supplied from a monocyclic generator or a special teaser winding. To go into a scientific explanation of this feature is outside the scope of this article, but we may briefly explain it by stating that since the field of the three-phase induction motor is supplied with a single-phase current, the three windings on the armature successively cut the magnetic field generated by the single-phase current, and consequently in the armature is induced a three-phase E.M.F. and current. This counter E.M.F. of the armature consequently induces a three-phase E.M.F. in the field. The interaction between this induced three-phase and impressed single-phase gives an E.M.F. of practically a three-phase relation at the field terminals.

The output of induction motors, when used on the monocyclic system, is about the same as when used on the three-phase system. The current required at light load, the efficiency, the power factor and the apparent efficiencies are practically of the same magnitudes.

Fig. 31 shows how the transformers supplying power to induction motors operated on the monocyclic system are connected. It is seen that the primaries of the two transformers are connected in series, and secondaries are connected in a reversed relation to each other. The teaser wire is brought over to the connection between the two transformer primaries and the two mains to the outside of

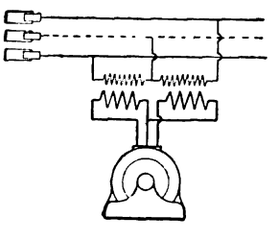

Fig. 31.

the two transformers. In the secondary circuit the wire coming from the common connection of the two transformers is practically the return wire for the other two, and consequently carries considerably more current than those—in fact, about twice as much.

In the primaries leading to the induction motor the currents vary considerably, depending upon the load of the induction motor and the condition of the external circuit. It is better not to operate motors from the transformers carrying lights, since the drop in the transformer will vary due to the variation of load on the motor.

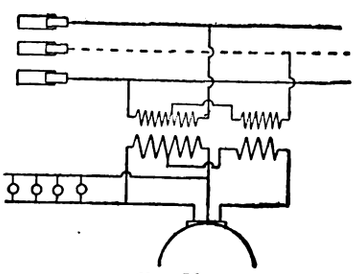

Fig. 32.

If the power is supplied through a secondary network—that is, if the entire power is distributed from, say, one or two large transformers—motors might be operated from these secondary mains. To do this the connections shown in Fig. 32 should be used.

*(To be continued.)*

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**(To-day) FRIDAY, May 29th.**

INSTITUTION OF ELECTRICAL ENGINEERS.

*4 p.m.* Special General Meeting of Members only at the Offices of the Institution, 28, Victoria-street, S.W., to consider alterations in the Articles of Association of the Institution.

**SATURDAY, May 30th.**

INSTITUTION OF JUNIOR ENGINEERS.

*10:30 a.m.* Visit to the Fowler-Waring Cables Works, North Woolwich.

**MONDAY, June 1st.**

SOCIETY OF ENGINEERS.

*7:30 p.m.* Ordinary Meeting at the Royal United Service Institution, Whitehall.

SOCIETY OF CHEMICAL INDUSTRY.

*8 p.m.* Meeting at Burlington House. Paper to be read: "The Electro-Deposition of Zinc," by Sherard Cowper-Coles.

**TUESDAY, June 2nd.**

INSTITUTION OF CIVIL ENGINEERS.

*8 p.m.* Annual General Meeting of Corporate Members only, to receive the Report of the Council and to elect the Council and Auditors for the ensuing year.

**FRIDAY, June 5th.**

ROYAL INSTITUTION.

*9 p.m.* Evening Discourse: "Electric and Magnetic Research at Low Temperatures," by Prof. J. A. Fleming.

**ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced).** Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

**ELECTROMAGNETIC THEORY.** By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

**THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE.** By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

**ELECTRIC LAMPS AND ELECTRIC LIGHTING.** By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

**MAGNETIC INDUCTION IN IRON AND OTHER METALS.** By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

**ELECTRIC MOTIVE POWER.** By A. T. SNELL. 10s. 6d.

**THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical).** By Dr. GEORGE GORE. Price 10s. 6d., post free

**ELECTRO-CHEMISTRY.** By Dr. GEORGE GORE. Price 2s., post free.

**PRACTICAL NOTES FOR ELECTRICAL STUDENTS.** By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free

**DRUM ARMATURES AND COMMUTATORS (Theory and Practice).** By F. M. WEYMOUTH. Price 7s. 6d., post free.

**THE INCANDESCENT LAMP AND ITS MANUFACTURE.** By GILBERT S. RAM. Price 7s. 6d., post free 8s.

**A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ.** By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

**"THE ELECTRICIAN" PRIMERS.** In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

**THE WORK OF HERTZ.** By Dr. O. J. LODGE. Price 2s. 6d.

**A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c** By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

**THE MANUFACTURE OF ELECTRIC LIGHT CARBONS.** A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

**THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS.** Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

**SUBMARINE CABLE LAYING AND REPAIRING.** By H. D. WILKINSON. *[Nearly ready.*

**MOTIVE POWER AND GEARING.** By E. TREMLETT CARTER. *[In preparation.*

## EVOLUTION IN ENGINEERING.

In his recent "James Forrest" lecture, Prof. A. B. W. KENNEDY suggested that there is "something in relation to things inorganic which closely resembles the position of natural selection in the organic world," and proposed the "working out of a theory of evolution in relation to engineering progress." Such a theory, fully developed, might fill a ponderous tome, and the space which can be devoted to it in a leading article is altogether inadequate; but we propose to draw attention to some of its more salient features. In the form suggested by Prof. KENNEDY, the relation of engineering evolution to organic evolution is merely a parallel or analogy. He sees in the development of machinery and engineering arts something akin to the forces of natural selection and of the struggle for existence which mould and fashion the world of organic species. But to us it appears that in the science of engineering evolution there is more than this. It was far more than a mere parallel between the laws of human society and the laws of all organic life that Mr. HERBERT SPENCER drew in his "Sociology"; it was a discovery of their identity—of the inclusion of the lesser within the greater. Social evolution exhibits not parallel but identical laws with biologic evolution, because human society is one of many organic species, and its customs are but the habits of one particular form of life. Now, the development of the engineering arts marks the progress of one department of social need, in human life, together with the manner in which the need, from time to time, has been more or less completely satisfied. Engineering, therefore, is but a branch of sociology and consequently of biology; it is the science of one set of habits, of one form of living organism. Accordingly, it should not surprise us when we find that the laws of evolution which operate over the entire universe of bioplasm also operate in engineering. To properly understand that this is so we have only to transfer our thoughts from the

Digitized by Google

human species to some lower form of life, such as the ant or the beaver. Antic or beaver engineering is admitted without hesitation to be the legitimate study of the biologist. And, though transcendently higher in its achievements, the purpose of human engineering does not differ, in its relation to the species which carries it on, from that of the interesting operations of the beaver or the ant.

Before attempting to discuss in detail some of the instances where the laws of organic life are discernible in engineering, we may direct attention to some of the popular errors regarding those laws themselves. To the man in the street evolution means only two things: the survival of the fittest, in the sense of the *best*, and the descent of mankind—from monkeys. Science, we need scarcely say, knows nothing of either of these two extraordinary ideas. Confusion between "fittest" and "best," as regards evolution, is very common, even among educated people, and Prof. HUXLEY was at great pains to make clear the distinction between them. If, as has been predicted, the future has in store an earth inhabited only by gigantic land-crabs, it would scarcely be flattering to then extinct humanity to call this species the best, though it undeniably would be the fittest for the occasion. Nor in the Reign of Terror or in the Indian Mutiny were the murderous outlaws the best, though indisputably they had better adapted themselves to their environment at the moment than the unhappy people whom they butchered. The fittest is often the worst, and it will always be so in a decadent environment. Nor is the distinction between "best" and "fittest" any less necessary when we look for evolution in engineering. Speaking of engineering productions, Prof. KENNEDY said: "There is also among them a survival of the fittest, and the laws which determine what is the fittest at any time and how the standard of fitness alters as time goes on are probably capable of fairly exact statement." As instancing one particular example of adaptation, these remarks are scientifically correct; but if we were to interpret them to mean that among any class of engineering products—say, boilers, dynamos or engines—there was a tendency for the best to survive, the facts would often be against us. Where Ignorance is the chief customer, it is folly for the manufacturer to be wise. At a time when prejudice controls the market salesmen naturally push their most successful wares, even though these may be intrinsically inferior in quality. Moreover, copious advertising and large capital interests will often give to an inferior article an additional impetus that will enable it to win the race with better goods. In such a case it is the fittest, but certainly not the best, that survives.

Another element which reduces engineering work from the ideal best to the sordid level of the commercially fittest is the influence that competition exerts upon manufacturing processes. Take as an example the selection of an engine. Ideally, that engine should be designed in all its details to be best adapted to do the work for which it will be employed. Practically, in the majority of cases, it is chosen from a number of stock sizes and patterns duly set forth in the makers' catalogues. And, in order that prime cost and the cost of repairs may be reduced to a minimum, all these stock pieces of machinery are so increasingly being made with interchangeable parts, by template, gauge and jig, and the details are machine-finished so accurately before being sent to the fitting shop, that the survival of the fittest in this instance threatens the complete extinction of the fitter. This practice is more to be regretted in some branches of mechanical engineering than in others. In the manufacture of hydraulic turbines, for example, it has largely been adopted in America, and the fashion is unfortunately being followed by turbine makers in this country; yet, of all forms of engines, water motors most require to be specially constructed to suit each individual works.

This compulsion to build only standard sizes and patterns of machinery, which in certain circumstances the struggle for existence has wrought in manufacturers, is also continuously modified by a process of natural selection, which brings about an adaptation of the standard patterns to the most common requirements, and produces in them, from time to time, such changes as are necessary on account of gradual variations in the demand. Thus old types vanish and new ones appear. And thus, too, unless they keep pace with the times, old firms vanish and new ones spring into existence. Not an insignificant illustration of this fact is shown by the rapid growth in modern times of steam engineering firms who have adapted themselves to the novel requirements of the electric supply industry. Older firms apparently were prejudiced with the old-fashioned notions of steam practice; and believing with foolish fondness that the electrical industry would have to follow along the old lines, they let the chance slip between their fingers. And precisely as this has happened in the electric supply industry, so does it promise to occur in regard to electric traction. Unless steam engine builders are prepared to supply engines which are electrically best, *i.e.*, fittest for the purpose of an electric traction station, the manufacture of such engines will drop out of their hands. But, after all, it requires no theory of evolution nor science of biology to teach us that.

From the relation of the detailed laws of organic evolution to the success or failure of any given branch of engineering work, let us turn to consider the science of engineering in its relation to the most general law of evolution, whether social, organic or cosmic, that has yet been formulated. We refer to the principle which HERBERT SPENCER has described as being embodied in "a progress from a state of undifferentiated homogeneity to a state of highly differentiated heterogeneity." Whether we consider the evolution of stellar and solar systems, of organic species or of social communities, we find that the progress is the one indicated in the law just enunciated—one of change from simplicity of structure to highly complex structure; and we find the same when we turn either to engineering as a whole or to any one or other of its manifold branches. In a leading article which we published in our issue of July 13, 1894, we directed attention to the manner in which this generalised law is exhibited in the evolution of machinery. We showed that, contrary to the popular view of the matter, machinery does not tend to develop into more and more simple forms, but rather into forms of higher complexity. As an illustration, we cited the engines of an ocean-going steamer. In the earliest steamers the machinery was of a simple kind, and the number of working parts was smaller than in a first-class liner of to-day. While there is always in machinery a tendency to simplicity of function of each separate detail, *i.e.*, while the tendency is to reduce the number of duties of each element of the machine as much as possible—there is a corresponding tendency to multiply the number of parts.

In this broadest aspect of the subject it would have been possible for Prof. KENNEDY to have discovered a further relation between physical experiment and engineering, and thus for him to have combined the subject upon which he had desired to speak with that on which he did speak. For, from the progress of physical science which has been a direct consequence of experimental investigation, engineering has received some of her richest accessions of territory. Or, to put the matter more into the language of evolution, it has

Digitized by Google

been the impetus afforded by experimental research that has produced the larger part of the evolution of engineering from "a state of undifferentiated homogeneity to a state of highly differentiated heterogeneity." We will cite a few illustrations in support of this. Through physical research on the properties of steam and on the manufacture and strength of iron and steel, engineering has acquired her departments of steam engineering and railroading; the experiments on and with primary batteries added telegraphy; the researches of HENRY and of FARADAY contributed the possibilities of telephony and heavy electrical engineering; later researches of modern physicists and engineers have enlarged the sphere of engineering by the departments of electric traction, polyphase transmission, electro-chemistry, &c. In all these instances, and in an immense number which we have not space to cite, the progress of engineering has been assisted by experimental research, and that progress in each and every case has been one of evolution along the lines indicated by the great general law already enunciated.

## THE MAXIMUM EFFICIENCY OF TRANSFORMERS.

BY BERNARD P. SCATTERGOOD, M.A., OXON.

In designing a transformer to fit a particular load-curve, it is obviously desirable so to arrange matters that the mean efficiency of the transformer, when averaged over a whole day's output, is as high as possible. The point, however, at which the efficiency of the transformer ought to be a maximum, will vary with the form of the load-curve. In sub-station transformers, for instance, which are switched on and off the circuit to suit the load on the mains, and are worked at as nearly full load as possible, the efficiency should clearly, for economical working, be a maximum at or near full load. On the other hand, in house transformers, where for a great part of the day the load is very small, it will pay the central station to have the maximum efficiency occurring at half-load, or even less. In all cases a transformer should be so designed as to give its maximum efficiency at or near that load which will give the greatest economy in working, when the nature of the variations of load is taken into consideration. The simple results which are worked out below are not, perhaps, very generally known, and will be found useful. Their application would, for instance, prevent the possibility of such an anomaly as a transformer whose maximum efficiency occurs at a load which is beyond the safe carrying capacity of the wire with which it is wound.

The problem is, to determine the conditions of maximum efficiency in a transformer. Now, in a transformer the total losses are made up of the losses in the iron core (hysteresis and eddies) which may be considered, to a first approximation, as constant at all loads,—and of the copper losses, which vary as the square of the current in the secondary, unless the power-factor of the transformer be very small. In this latter case the effect of the magnetising current in increasing the copper losses in the primary coils will have to be allowed for. In dealing, however, with a closed-iron circuit transformer of good design, in which the magnetic leakage is small and the power factor large, the above statement is practically correct. Writing $w$ for the iron losses in watts, $p\,C^2$ for the copper losses when a current C is passing though the secondary, and E for the secondary terminal voltage under the same conditions, we have as the expression for the efficiency at a secondary output of E C watts,

$$\eta = \frac{E\,C}{w + p\,C^2 + E\,C}.$$

It is easily seen that $p$ in the above equation is equal to $r_1\zeta^2 + r_2$, where $r_1$, $r_2$ are the hot resistances of the primary and secondary windings respectively, and $\zeta$ is the conversion ratio of the transformer. The "conversion ratio" I define as the number which expresses the ratio between the secondary and the primary terminal voltages, at a given load. The "constant" $p$ is thus really a function of the resistances of the primary and secondary windings, and of the secondary terminal pressure of the transformer. Of course, strictly speaking, $r_1$ and $r_2$ are themselves functions of the current C, since the resistance varies with the temperature of the wires, and therefore with the current; but it will not introduce a serious error if the temperatures of the windings are estimated and the resistances $r_1$ and $r_2$ are calculated on this basis and treated as constant. We may also neglect the drop in E.M.F., and take E as being equal to the open circuit voltage of the transformer, and therefore a constant. In this case $p$ will also be a constant. This, again, will not introduce a serious error, especially as the lessened values of $p$ and E, when the drop in E.M.F. is taken into account, tend to cancel each other; but if it is thought necessary, both in this case and in that of the resistances, after a first approximate determination has been made of the value of C which will make $\eta$ a maximum, the value of C thus obtained may be used to determine more accurately the values of $r_1$, $r_2$ E and $p$, and by the substitution of these corrected figures a more exact evaluation of C may be obtained by the method of successive approximations. It will be found, however, that in practice this is a quite unnecessary refinement.

In the expression, then, for the efficiency given above, we have $w$, $p$, and E constants, the only variable being the current C. To find the value of C which makes the efficiency a maximum, we differentiate with respect to C, and equate the resultant expression to zero. We thus obtain—

$$\frac{1}{E}\frac{d\eta}{dC} = \frac{1}{w + p\,C^2 + E\,C} - \frac{2\,C^2 p + E\,C}{(w + p\,C^2 + E\,C)^2}$$

$$= \frac{w - p\,C^2}{(w + p\,C^2 + E\,C)^2} = 0.$$

Thus, for the efficiency to be a maximum it is necessary and sufficient that

$$w - p\,C^2 = 0,$$

or

$$w = p\,C^2.$$

That is to say, the *condition for maximum efficiency is, that the copper losses should be equal to the iron losses.*

Making $w = p\,C^2$ in the expression for the efficiency given above, we obtain as the value of the maximum efficiency—

$$\eta_{max.} = \frac{E\,C}{2\,p\,C^2 + E\,C},$$

$$= \frac{E}{E + 2\,p\,C},$$

C being determined by the equation

$$p\,C^2 = w$$

or

$$C = \sqrt{\frac{w}{p}}.$$

Hence

$$\eta_{max.} = \frac{E}{E + 2\sqrt{p\,w}}.$$

As an example, take the following case of an actual transformer:—

Iron loss on open circuit $= w = 140$ watts.
Primary resistance, hot $= 1{\cdot}75$ ohms.
Secondary resistance, hot $= 0{\cdot}006$ ohms.
Ratio of conversion, from 2,000 to 102 volts at no load $= \frac{1}{19{\cdot}61}$.

Hence $p = 0{\cdot}01055$, and the load at which maximum efficiency is reached is—

$$C = \sqrt{\frac{140}{{\cdot}01055}} = \sqrt{13270} = 115 \text{ amperes, nearly.}$$

Also the efficiency at this load is

$$\eta_{max} = \frac{102}{102 \times 2\sqrt{140 \times 0{\cdot}01055}}$$

$$= \frac{102}{104{\cdot}43} = 97{\cdot}67 \text{ per cent.}$$

To show the small error which is introduced by taking in the above formulæ the open circuit value of the voltage,

Digitized by Google

instead of the value as affected by the drop, we will work out the drop and make the calculation of the efficiency afresh.

We find, then, that the drop in E.M.F. due to the secondary resistance is

$$115 \times 0{\cdot}006 = 0{\cdot}69 \text{ volts},$$

while that due to the primary resistance is

$$\frac{115}{19{\cdot}61} \times \frac{1{\cdot}75}{19{\cdot}61} = 0{\cdot}523 \text{ volts}.$$

Thus the total copper drop = 1·213 volts. There remains the drop due to magnetic leakage. This must be estimated by a comparison of the behaviour of similar types of transformers. In the one we are considering, 0·4 or 0·5 volts would be a fair estimate; we get then for the total drop at 115 amperes 1·213 + 0·5, or say 1·7 volts. E then becomes 102 – 1·7 or 100·3 volts, and a recalculation of the maximum efficiency with this correction gives us

$$\eta_{max} = \frac{100{\cdot}3}{100{\cdot}3 + 2\sqrt{140 \times 0{\cdot}01055}}$$

$$= 97{\cdot}63 \text{ per cent.}$$

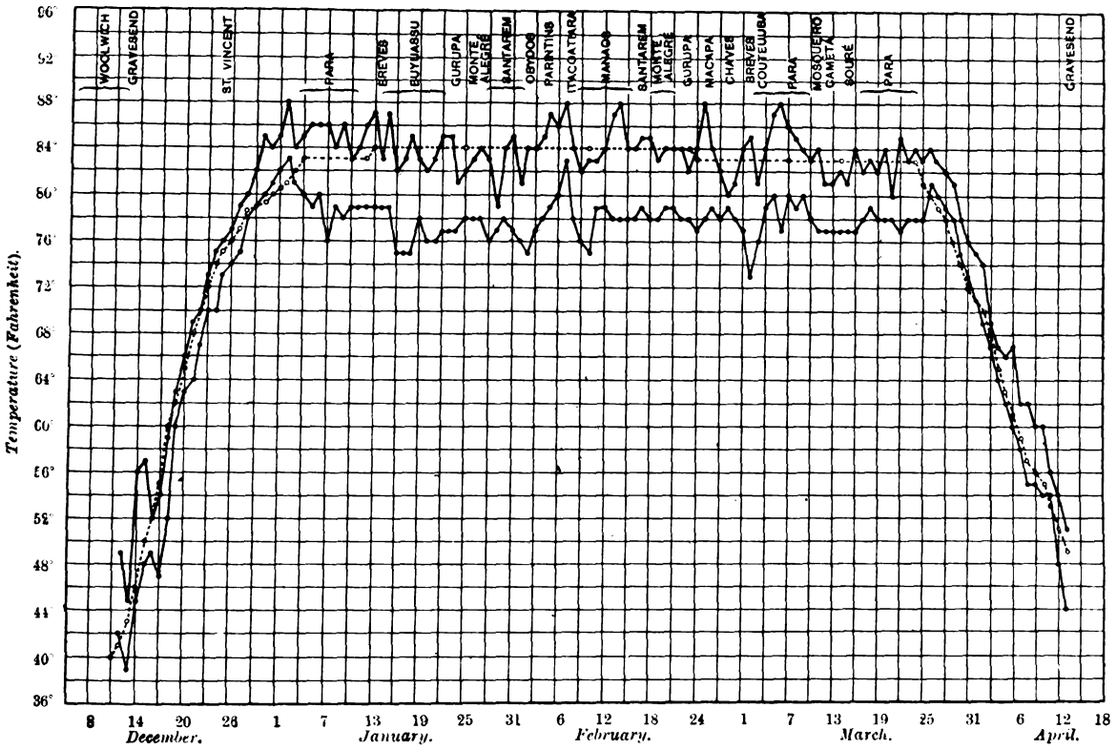
or practically the same value as that obtained when the open-circuit value was taken, the drop being neglected. If we substitute in this last equation the corrected value of $p$, that, namely, corresponding to a secondary terminal pressure of 100·3 instead of 102 volts—that is, if we substitute 0·0104 for 0·01055—the value of $\eta_{max}$ works out to 97·65, which is still nearer to the figure obtained by the approximate formula given above.

These very simple formulæ, then, namely, $C = \sqrt{\frac{w}{p}}$ and $\eta_{max} = \frac{E}{E + 2\sqrt{pw}}$, may safely be used to determine the conditions of maximum efficiency, and ought to be familiar to all who are concerned either in the designing or in the practical running of transformers.

**The Utilisation of Niagara.**—An extra Friday evening meeting of the members of the Royal Institution will be held on June 19th, when Mr. Thomas C. Martin, one of the editors of the *Electrical Engineer* of New York, and American delegate to the Kelvin Jubilee, will deliver a lecture on "The Utilisation of Niagara."

## THE AMAZON CABLE EXPEDITION.

Some particulars of the system of telegraph cables which has recently been completed by Messrs. Siemens Bros. and Co. in the Amazon River and its tributaries were given in our issue of March 20th (Vol. XXXVI., p. 681), and in our last issue we gave some account of Mr. Alexander Siemens' recent lecture on the subject. Through the kindness of Mr. Siemens we are now enabled to publish a reproduction of the curves of temperature readings which were taken during the expedition when the cables were laid. The upper of the two full-line curves gives the maximum, and the lower of these the minimum temperature of the air, while the dotted line gives the temperature of the water. The curves give the readings both on the outward and return voyages, and include the ocean temperature readings between England and Pará.



Temperature Readings taken during the Amazon Cable-Laying Expedition (1895-6).

## SOME EXPERIMENTS WITH HITTORF TUBES AND RÖNTGEN RAYS.*

BY ANTONIO ROITI.

The Accademia dei Lincei at Rome permits me to show to it some of the many experiments which I have made in this matter, although they are still imperfect and poor in comparison with the labour which they have cost, and although I may have been anticipated by others who probably have succeeded better than I.

1. *Shadows and Penumbras.*—Röntgen says that the X-rays proceed from that point where the side of the tube is struck by the cathode rays, and adds that if the internal rays are turned aside by a magnet, the X-rays proceed from another point, which in its turn is the end of the cathode rays. All other observers confirm this circumstance; some suppose that the cause of the Röntgen rays is the fluorescence generated in the glass by the cathode rays, others believe that such fluorescence is a necessary condition of their emission, a few others are more reserved, and among these last am I, who incline to consider the fluorescence a purely concomitant phenomenon.

But before treating this question I have wished for my own satisfaction to try to determine the geometrical point whence the Röntgen rays emanate and the manner of their emission. The X-rays proceed from the side of the tube; but do they come from any point of it as prolongations of the internal cathode rays, or do they emanate from the wall of the tube in a normal direction or in all directions?

* Rendiconti della R. Accademia dei Lincei. Read March 1, 1896.

Digitized by Google

It occurred to me to observe the shadows and the penumbras caused, and, in fact, limiting the radiating points with suitable metallic screens, suitably pierced, I am persuaded that the penumbras are always there, even if the cathode rays proceed from one point, however short the distance of the opaque body from the shutter. At first sight, one might think that this was a phenomenon of diffraction, since there are nearly always alternations of greater and lesser intensity in the penumbras; but it is necessary to proceed cautiously, knowing that the internal cathode rays are reflected by metal and glass. The matter is complicated, and doubt is justified by our ignorance with regard to the wave-length, since the outlines may be lost with high frequencies if the rate of propagation is very great.

At all events I have attempted to reduce to a point the place of the emanation of the X-rays, taking for cathode a spherical mirror with the centre of curvature on the side of a glass bulb.*

The bulb is represented a third of the natural size in Fig. 1. Its concave mirror of aluminium has a radius of curvature of 40mm.; the filiform anode is placed in the little side tube. After I had exhausted it as highly as I possibly could, it showed a splendid fluorescence, but displayed it over the whole of its surface and with somewhat greater intensity in the tubulure containing the anode. I noted incidentally that, having put the anode in communication with the gas pipe, the fluorescence was concentrated over the hollow surface opposite the cathode, ready to shine everywhere if I breathed on the bulb. Then, immersing the bottom of the bulb in water deposited over a very thin plate of mica the fluorescence disappeared as if internally. In these conditions I have been able to obtain well-marked impressions whilst the objects were close to the photographic plate, but they disappeared when they were distant from it. For example, a metal grating with a mesh of 1mm., inclined at 45deg. to the plate and to the axis of the mirror, has only given very distinct shadows at points immediately adjacent; but at about 1cm. from the plate the meshes were hardly to be distinguished, and the plate was about 14cm. from the bottom of the bulb.

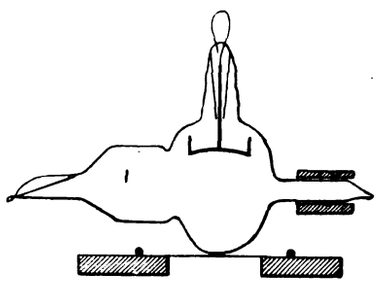


FIG. 1—(One-third actual size).

Do the disappearances arise perhaps from the circumstance that the rays proceed only from that single point of the bulb where the centre of the curvature of the cathode rays is situated, or from the periodicity of an action not regular enough to give the diffraction fringes, but sufficiently long in time to disturb the accuracy of the outlines?

A little electric lamp, with a ground-glass bulb of the same size as the bulb employed, placed at the same distance, gave me the shadows almost as ill-defined as those made on the aforementioned plate. And although the conditions might not be identical, because the lamp shone all round about, whilst the bulb was slightly fluorescent only in the immediate vicinity of the centre of the mirror, yet it appears to me that also in the case of the Röntgen rays the disappearance may be attributed to the diffusion from the glass wall, which in order to emit them does not need to be fluorescent.† In confirmation of this I can mention shadows with well defined outlines which I have obtained even at a considerable distance, when I have limited the radiating point by a screen having a small aperture. But of this I shall speak later on.

2. *The behaviour of a Tube during Exhaustion.*—The tube which I call H (Fig. 2) is cylindrical, 150mm. in length and of 40mm. in diameter. It has a spherical mirror with a radius of curvature of 4cm., and the centre of curvature is in the centre of a ring of aluminium wire, which serves as anode. From the mirror to the bottom of the tube, which is a spherical cup, is 122mm.

I have used this tube, keeping it always attached to an excellent Geissler pump so as to vary the rarefaction at pleasure. To enable me to follow the various phases of luminosity, I inserted it in series with a spark-gauge with balls, on the secondary of a large Ruhmkorff coil excited so as to give, with a rapid Deprez interruptor, sparks of 6cm. in air between the points. The insertion of the spark-gauge (spinterometer) is necessary, if in the first stages one wishes to eliminate the luminosity produced by the current at "make," which by the persistence of the images on the retina may be superimposed upon the luminosity evoked by the currents at "break." The mirror was the cathode for these latter currents, and the anode was the ring communicating with the spark-gauge.

I pass over the preliminary stages, in which the positive luminosity is still visible, and confine myself to the *first stage* of the negative luminosity only, in which one may begin by distinguishing three bands—the first nearest to the cathode, and of a tan colour; the second is called the dark space, but it is really, as Goldstein has shown, of a blue colour; the third band, more brilliant than the first two, is of various colours, according to circumstances, violet in rarefied air, whitish for the most part when all the air has been extracted and the tube is affected by the air already absorbed by the electrodes and by the glass.*

In this first stage the second band forms the double bluish cone with a vertex in the centre of the curvature of the mirror; it passes beyond the whitish luminosity, and where it comes in contact with the glass it causes fluorescence, much more vivid at the bottom of the tube, which is heated to such a point as to appear red for a moment, when the discharge is discontinued.

Increasing the exhaustion, the third band enlarges; it grows paler and finally disappears. Here, we may say, commences a *second stage*, in which one can bring the balls of the spark-gauge into contact with-

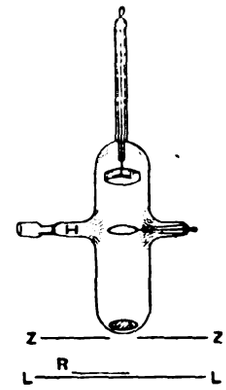

FIG. 2.

out the anode becoming luminous. The vertex of the double blue cone is no longer in the centre of curvature, but more distant from the cathode, and the tan colour of the first band is prolonged. The fluorescence becomes more intense along the walls ascending from the bottom, and the bottom of the tube falls in temperature so that one can touch it without scorching oneself. With the disappearance of the whitish light, which is characteristic of the *second stage*, the bottom of the cryptoscope coated with platino-cyanide of barium begins to be plainly seen, and so one may say that the Röntgen action proper† really begins from this point onward.

* I have had to surmount great difficulties in the construction of these vacuum tubes, but after innumerable failures Signor Adolfo Calamandrei, curator of the Museum of Ancient Instruments, although inexperienced, commenced with great perseverance to try, and has succeeded in blowing such a tube as I require, and which is sufficiently regular. It is fitting that I should express my thanks to him for it.

† As a matter of curiosity I show the print of a shadow of nuts, walnuts, almonds and chesnuts in their shell, obtained when the bulb was hardly luminous at all. Leaves of the oleander and the ilex have left on the negative some light traces of their venation; and it is certain that lovely photographs of the skeletons of leaves can be obtained in this way, by suitably varying the length of exposure.

* This whitish luminosity is most difficult to eliminate, especially if the tube has been long in communication with the atmosphere. I have had for several years a tube made open for me by Müller, of Bonn, and never exhausted. Now, after a prolonged working of the mercury pump, making the electric discharge pass through without stopping, I have succeeded in making it assume a lovely green phosphorescence, and in obtaining a well-marked photograph; but since then the whitish luminosity has again appeared, and the tube is no longer efficacious. And this has repeated itself three times after exhaustion. It is by the colour of the luminosity that I judge whether a tube is spoiled, perhaps by the opening of some very small pore, or whether it arises from air already condensed in the interior: the colour is violet or reddish in the first case, whitish in the second. Useful precautions to make a tube last are to make it red-hot all over whilst it is being blown, and to connect it with the pump without delay, or even to keep it hermetically sealed. During the action of the pump it is best to continually pass through the tube alternate discharges, stronger and more frequent than those which are to be sent through after detachment from the pump. I may here mention the case of a Bessel-Hagen pump, which I left unused for some years communicating with the atmosphere, because there was no mercury in it. With it, although it has remained perfect, I have never yet succeeded in eliminating entirely the whitish luminosity of the third cathode band, and I kept it in action for about a week!

† *Added in the correction of the proofs* (March 5th).—I have obtained a photograph also from a tube which was in the first stage, and was all filled with the whitish luminosity; but‡ this was on condition that I sent some sparks 4cm. long through the air in front of the anode. Suppressing these sparks, there was no photograph in spite of a long exposure.

[‡ Exact meaning of original not very plain.—ED. *E.*]

Digitized by Google

Pushing the rarefaction still further, the double cone continues to taper off more; it also grows pale, and becomes invisible, and at last even the tan-coloured aureole almost disappears where it spread right up to the concavity of the cathode. In this *third stage* the brilliance of the lateral walls and that of the cryptoscope are at a maximum; the bottom of the tube is hardly warm and scarcely shines, it has also the appearance of being stained by a coffee-coloured fluid which rises up in the way in which alcohol rises when thrown to the bottom of a cup filled with water.

Continuing to pump in this third stage, which I consider the most efficacious, the passage of electricity becomes more difficult. There may occur, as it were, palpitations, in connection with which some sparks light up the external wall of the tube without detaching themselves from the electrodes, and the external conductors of the tube send out splashes of purplish light. But before this the fluorescence becomes paler on the lateral walls, and returns to the terminal basin, and the field of the cryptoscope continues to grow weaker. Two other tubes were also followed by me through all these phases of luminosity.

3. *Shadows Directly Magnified.*—I have placed the tube H horizontally, I have arranged at 5mm. from its bottom the slit of a diffraction bench giving it the width of 1mm.: at 48mm. from the slit placed parallel with it, a screen formed of threads of copper so thin that there were only 25 of them in 20mm. Behind the screen and at various distances I placed the photographic plate wrapped up in several folds of black paper.

In taking the photograph I was careful to maintain the exhaustion in its third stage, in such a condition that the tan-coloured aureole could no longer be seen, and all the walls had an intense fluorescence. In order to do this I was obliged to work the pump frequently, since the prolonged discharges altered the condition of the air inside. Under these conditions, and with a rapid interruption, I obtained among others the two photographs *p* and *q*, which

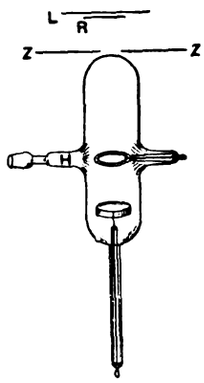

Fig. 3 (One-sixth actual size).

I show, and with slow mercury interruptor the photograph *r*. For the photograph *p* the distance between the screen and the plate was 13mm.; for photograph *q* it was 96mm., and for *r* 120mm.

We are still far from *magnifying the invisible*, but at any rate we have obtained a magnification from two to seven with outlines quite well defined.

4. *Fluorescence does not appear to be a Necessary Condition for the Emission of Röntgen Rays.*—It appears to me that we may conclude from what precedes that the waves (if they are waves) of the Röntgen rays must be short, and I maintain that I have proved that the disappearance of the shadow, as in the case of the bulb I, may be ascribed to the great size of the emitting surface, although the fluorescent portion may be very small.

My other experiment seems to me to shew that Röntgen rays can be produced without fluorescence. In the tube H described before, a disc of mica was enclosed which, in the horizontal position before adopted, did not intercept the cathode rays. When, however, the tube was vertical and the disc supported on the bottom as in Fig. 2, or on the ring as in Fig. 3, the discharge heated the mica all round its centre to a bright red, but the green fluorescence did not reach so far. It was impossible for me in these circumstances to pass from the second to the third stage. It was impossible, therefore, to make the double cone disappear, although it was much tapered off.

In the arrangement shown in Fig. 2 I had placed at 3mm. from the end of the tube a zinc diaphragm Z Z with an aperture 18mm. in diameter; and below, at the distance of 22mm., a piece metal gauze R, which only covered about half of it, and was supported directly on the black paper which enveloped the photographic plate L L with many folds. The positive *a* is taken from the impression obtained in this manner.

In the arrangement shown in Fig. 3 the tube was upside down, having been turned round upon the tube which joined it to the pump, and the disc of mica entirely covered the ring which formed the anode. When matters were so arranged the red-hot part was larger, although the mica was now in the centre of curvature of the mirror, which was made the cathode. As before, and at 3mm. from the end, was placed the screen Z Z with its aperture of 18mm.; and at 22mm. from it the gauze in immediate contact with the covering of the photographic plate L L. The positive print *b* shows the impression thus obtained, and comparing it with the positive *a*, it is seen that the active rays now proceeded from the glowing mica.

There is a confirmation of this in the print *c* produced by the arrangement shown in Fig. 4, in which the tube was put upright; the mica was on the bottom, as in Fig. 2 but the distances between, the mica and the screen and the plate were the same as those of Fig. 3. These distances being equal the impression is the same whether the mica is on the ring, or on the bottom of the tube.

*5. *Complications of Phenomena and the Necessity for Describing Minutely all the Circumstances in which the Observations are made.*—We must not pay attention in the preceding photographs to the relative intensity of the impressions, since there are too many circumstances which might cause it to vary, and are all not within control. Leaving out of consideration the duration of the action, the sensitiveness of the plate, the manner of developing it, the intensity, frequency and nature of the electric discharge, let us think of the variability of the glass (or, rather, in our case, of the mica which was undergoing disintegration) under prolonged action, of the continually changing condition of the air inside, which may be liberated or absorbed, of the conditions of insulation of the tube at its various points, and above all of the varied distribution of the

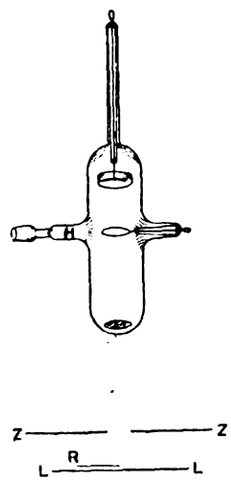

Fig. 4 (One-sixth actual size).

discharge and of the subsequent interrupted discharges which are usually noticed along the external walls of the tube, &c., &c. In view of all these things the diffidence with which at present I regard quantitative determinations in experiments of this kind is justified.

It would be desirable that observers should indicate at least the shape and dimensions of the tubes and electrodes, the stage of the luminosity at the moment of observation and the method of excitation. In this way any contradictory results would probably receive their justification as, for instance, the discrepant observations of Prof. Righi and Profs. Borgmann and Gerchun. The former found that under the Röntgen action an insulated metal sphere tended to acquire or to preserve a positive charge, whilst Borgman and Gerchun found a negative residual charge. In some cases I believe that by the use of an exploring point in the external field opposite effects might be observed even with the same tube excited in the same manner. I will give an example. A tube J (of external diameter 25mm., length 142mm.) had at the top as cathode a cup of 10mm. radius of curvature, height 8mm., and across the the middle for anode a ring coaxial with the cup. When excited with a rapid interruptor and with a large coil which gave a 6cm. spark in the air, it was found in the second stage of luminosity (that is to say, the third band had disappeared), that it showed hardly any trace of cathodic luminosity on the anode, yet it still showed faintly the luminosity of the second band forming the double cone with the vertex much further away from the centre of

* Although one might consider it superfluous, nevertheless for precision I wished to subject the plate, gauze and diaphragm in their relative positions, as in Fig. 2, to the action of a sheet of mica heated red-hot by a jet of flame, in such a way that it might present the same appearance as it did when it was glowing under the effect of the discharge in the inside of the tube. I did not obtain, as is readily supposed, any impression at all, although I prolonged the exposure for a very much longer time.

E

Digitized by Google

the cup. Exploring the field with the cryptoscope, the diaphragm was found to be more luminous in the centre than at the periphery whilst it was near the tube ; but when it was further off it appeared darker in the middle ; and this in any position with respect to the axis of the tube. This fact is hardly in agreement with any other fact, which appears very strange and evidently needs more study.

Some observations made by photography show, it appears to me, that the amount of transparency of certain plates may vary with the variation of their distance from the surface of emission of the X-rays. But I repeat that this fact has not been sufficiently investigated to exclude the possibility of some disturbing circumstance having arisen.

6. *Applications to Petrography.*—Finally, I may say that among the various slices of rock lent to me by the Royal Bureau of Mineralogy, I have met with some peculiarities in the jaspars, and I have begged Prof. Grattarola to study the question from the mineralogical aspect. The other rocks were not in sufficiently thin slices to give noteworthy differences.

The oriental gems, which I have tried in comparison with western ones of the same name, do not show differences of opacity sufficient to enable them to be discriminated in the same way as one recognises with certainty real diamonds from paste.

7. *Additions made on March 5th in Reading over the Proofs.*—During the last few days Signor Calamandrei has prepared for me two tubes similar to Fig. 2, but containing in one case a disc of platinum $\frac{1}{100}$mm. thick, the other a disc of porcelain, which I cut out from a Ginori plate and reduced to the unusual fineness of $\frac{1}{4}$mm. Both the discs were relatively larger than that of mica shown in Fig. 2, for they almost filled the section of the tubes. Both the tubes were excited with the rapid interruptor and the large coil, which gave sparks of 15cm. in the air. They were both kept between the end of the second and the beginning of the third stage of exhaustion, and with the arrangement of Fig. 2 they gave me photographs of a piece of metal gauze. The platinum glowed at the middle, and, becoming volatilised, blackened the lateral walls up to the height of the ring which formed the anode, whilst it left the lower hemisphere transparent.

To glass and aluminium are now to be added mica, platinum and porcelain as substances which emit Röntgen rays when exposed to cathode rays.

## THE UTILISATION OF WATER-POWER, ESPECIALLY WITH A SMALL FALL, WITH SOME EXAMPLES OF PLANTS FOR THE GENERATION OF ELECTRICAL ENERGY.*

BY ALPH. STEIGER.

The cheap production of electrical energy is generally recognised to be one of the chief aims of modern engineering science. Nature has provided us in water-power with one of the best possible agents for realising this object; and I trust that, in bringing the subject of the utilisation of this free gift of Nature before the members of the Institution of Electrical Engineers, I shall be able to convince them that the water-powers of this country, if judiciously utilised, are capable of rendering them great service.

In my own country—Switzerland—the electrical engineer is co-operating cordially with the water-power engineer, and electrical installations are rapidly increasing in number. The successful electrical transmission of power to points far distant from its source has been the chief factor in this development. The idea prevails that considerable fall is required to obtain water-power, but it is my desire to show and to *prove* in the following remarks that excellent results are obtainable also with a very low fall—a fall of even less than 3ft. Small falls are more frequently met with in this country than high falls, and will therefore have more particular attention in this Paper than the high falls found in mountainous districts. The description of a few turbine plants under low falls, some of which are applied to the generation of electrical energy, will be of special interest.

During a long experience in constructing turbines and designing complete plants I have found that the most difficult were always those connected with the utilisation of a low fall. These difficulties consist chiefly in the variation within very wide limits of both the quantity of water and the fall, while a constant power, and in most cases a constant speed, is of great importance.

Generally speaking, the real agent in water power is gravity, and the water is simply the medium to transmit the action of gravity on to the motor which converts it into mechanical work. The action of gravity can take either the form of dead weight, or of pressure, or of velocity, sometimes called kinetic energy. A very high efficiency is obtained from motors in which the water acts by dead weight or by pressure, but the slow speed of the water-wheels and the complicated mechanism of the pressure engines render them unsuitable for the purpose of generating electricity ; moreover, motors worked by weight or by pressure are only advantageous when working under a high fall. The kinetic energy is the only form in which the gravity can be applied advantageously to the performance of mechanical work under a small fall. The motors using it in this form are the common undershot wheel, the Poncelet water-wheel, and the turbines. It will be sufficient for the purpose of this Paper to give the efficiency of the various types of water motors for any fall, without going into a detailed description of those which are unsuitable for driving dynamos. The efficiency of the motors, with the fall for which they are adapted, is as follows :—

| Fall. Feet. | Efficiency of water wheel. | | Efficiency of turbine. |
|---|---|---|---|
| | | Per cent. | Per cent. |
| 1 to 5 | Ordinary undershot ... | 25 to 30 | 70 to 75 |
| | Poncelet ... ... | 65 to 70 | |
| | Sagebien ... ... | 65 to 75 | |
| 5 to 8 | Low breast ... ... | 30 to 50 | 75 to 80 |
| 8 to 15 | High breast ... ... | 60 to 75 | 75 to 80 |
| 15 to 50 | Overshot wheel ... | 55 to 75 | 75 to 80 |
| Above 50 | Pressure engine ... | 75 to 85 | 75 to 80 |

These figures show the interesting fact, that the smaller the fall is, the greater is the gain in power over the old-fashioned water-wheels. Although the smallest fall which would reasonably be utilised by a turbine is at least 2ft. 6in., I will show by some examples that, by a turbine suitably constructed and carefully adapted, useful power is still obtained under a fall of only 1ft. or a little over. The great variety of fall, water supply, local conditions, and special requirements, of necessity demands a variety of types of turbines.

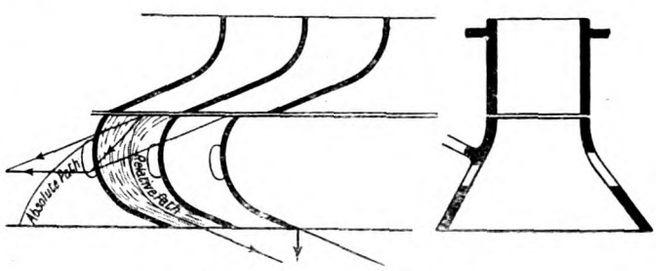

FIG. 1.—Vanes of "Action" Turbine.

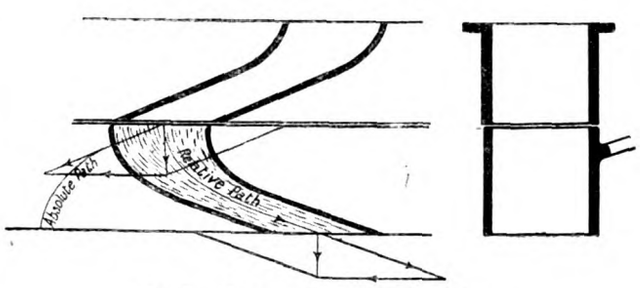

FIG. 2.—Vanes of "Reaction" Turbine.

Turbines are classified, according to the manner in which the water acts in them, into—(*a*) "impulse," or "action," turbines, and (*b*) "reaction" turbines ; and according to their construction, into—(*a*) parallel flow turbines, (*b*) radial flow turbines, (*c*) mixed flow turbines.

There is an essential difference between the "impulse" turbine and the "reaction" turbine, as indicated by the form of vanes illustrated in the diagrams Figs. 1 and 2.

The "*impulse*" *turbine*, as usually constructed, must run clear of the tail-water, its buckets being only partially filled with water. It requires a constant fall, with constant level of the water in the head and tail race, but its efficiency is not affected by the greatest variation of the water supply. On account of this quality, it can be built as partial injection turbine, to utilise high falls with a very small water supply. If constructed as "partial injection turbine," its diameter can be chosen so as to give just the desired number of revolutions. This is extremely convenient for driving dynamos, which can thus be connected direct with the shaft of the turbine, doing away with intermediate gearing or belt drives. An instance of this kind is the turbine plant now being erected by Messrs. Escher, Wyss and Co., of Zurich, at the Falls of Foyers, for the British Aluminium Company (Limited). This plant consists of five "impulse" turbines with vertical shaft, with partial injection, each giving 700 B.H.P., working under a fall of 350ft. The dynamos are required to run at 140 revolutions per minute, and to

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

obtain this speed the turbines were given a diameter of a little over 9ft.

Partial injection turbines under a high fall are sometimes fixed on a horizontal shaft, and can thus be coupled direct to the armature spindle of a dynamo by means of an isolating coupling.

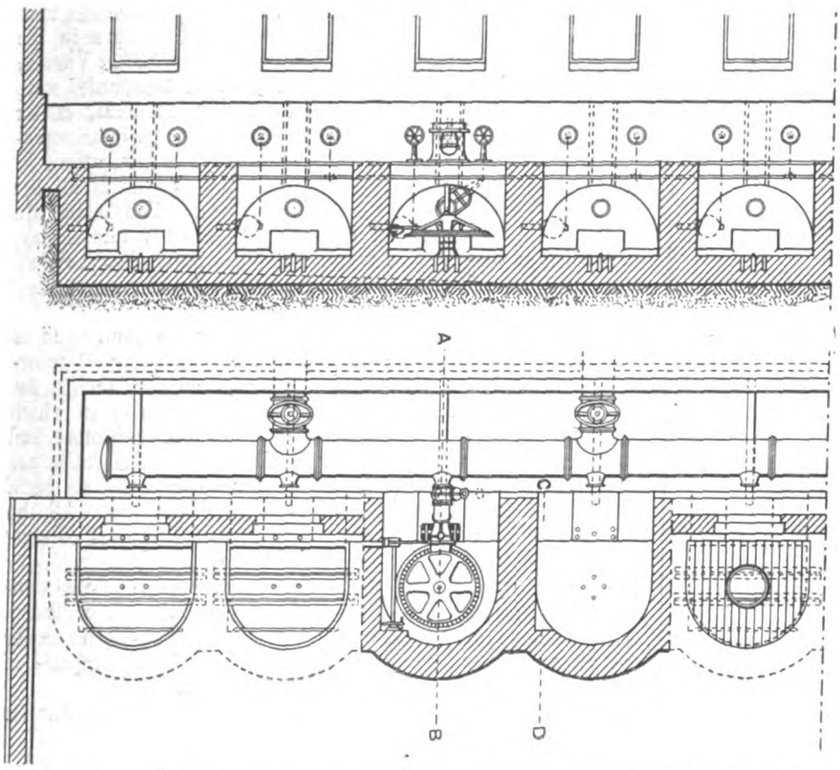

FIG. 3A.—Turbines at the Falls of Foyers, Scotland. (The British Aluminium Co., Limited.)

This mode has been adopted, amongst numerous other plants, for the electric lighting installation of Davos, in Switzerland, which consists of three horizontal patent turbines of 200 B.H.P. each, working under a fall of 330ft., and running at 400 revolutions per minute. The turbines have a diameter of 40in. As a contrast to these turbines of large power and small diameter, and to show the adaptability of the partial injection turbine to special requirements, the 140 H.P. turbines of the waterworks in Chauxdefonds may be mentioned. These work under a fall of only 170ft., but as they are driving pumps at the low speed of 60 revolutions they had to be made of a diameter of 15ft.

Great as the advantages of the "impulse" turbines are under the conditions above mentioned, their use under very low falls is limited, firstly, owing to the reason already given that they must run clear of the tail water—a condition which can seldom be realised in a flat country like this; and, secondly, because they run at a slower speed than a "reaction" turbine under the same fall. Although "impulse" turbines are now built to run in the tail water without considerable loss of efficiency, the reduction of power in proportion to the reduced fall, and the quantity of water accordingly reduced, together with the reduced speed, excludes them in the majority of low and varying falls. The ideal turbines for low and varying falls are *the "reaction" turbines.* They are generally placed on a level with the tail water, or, if local conditions require them to be placed above tail water, connected with it by a suction tube. They run at a higher speed for the same fall, or the same diameter, than an "impulse" turbine, and their efficiency is not affected by the immersion in the tail water. The principal objection raised against "reaction" turbines in general is that their efficiency is greatly reduced when working at part gate. This is indeed the case with many of the reaction turbines known in this country, which give a very poor efficiency at part gate, especially at less than half gate. The continuity of flow of the water through the buckets is essential to a good efficiency. Only in a few reaction turbines is this condition fulfilled to such an extent that within very wide limits of the water supply the efficiency is not perceptibly reduced.

The utilisation of a small and varying fall, with a varying quantity of water, is a very difficult problem for the water-power engineer. The turbine for a given power under a low fall is larger and runs slower than one of the same power under a higher fall; it is, therefore, heavier and more costly, and requires heavier gearing, entailing a greater loss of power through friction. A high speed is desirable, especially for driving dynamos; but attempts to increase the speed of the turbine by reducing its diameter may easily result in an inferior efficiency. The efficiency should be as high as possible in consideration of the greater cost of a water-power plant with a low fall; but the proportion within which such a fall and the quantity of water varies is mostly so great that it is almost impossible to obtain the highest efficiency when the water supplied is diminished, *i.e.*, when a high efficiency is most wanted. The maintenance of a *constant* power with a *constant* speed under variation of fall and quantity of water in large proportion can, if at all, only be attained by sacrificing some efficiency. The hydraulic losses must be reduced to a minimum by the most careful construction of the turbine in its essential parts, and it is needless to say that no standard size or type of turbine will fulfil all these conditions by simply consuming all the available water.

Even the arrangement of the turbine chamber is of influence on the results, and requires special attention. On a careful judgment of the local conditions depend the economy and the success of a plant. Unsatisfactory results in water-power plants are caused just as much, or oftener, by bad judgment of the local conditions as by the inferiority of the turbine. In by far the most cases of low falls incidental to flat countries, an abundance of water corresponds with a reduction of the fall. The power of a turbine calculated for the normal fall would be reduced, for the time, when an abundance of water reduces it, and, as a consequence, water would be wasted, while the power obtained is

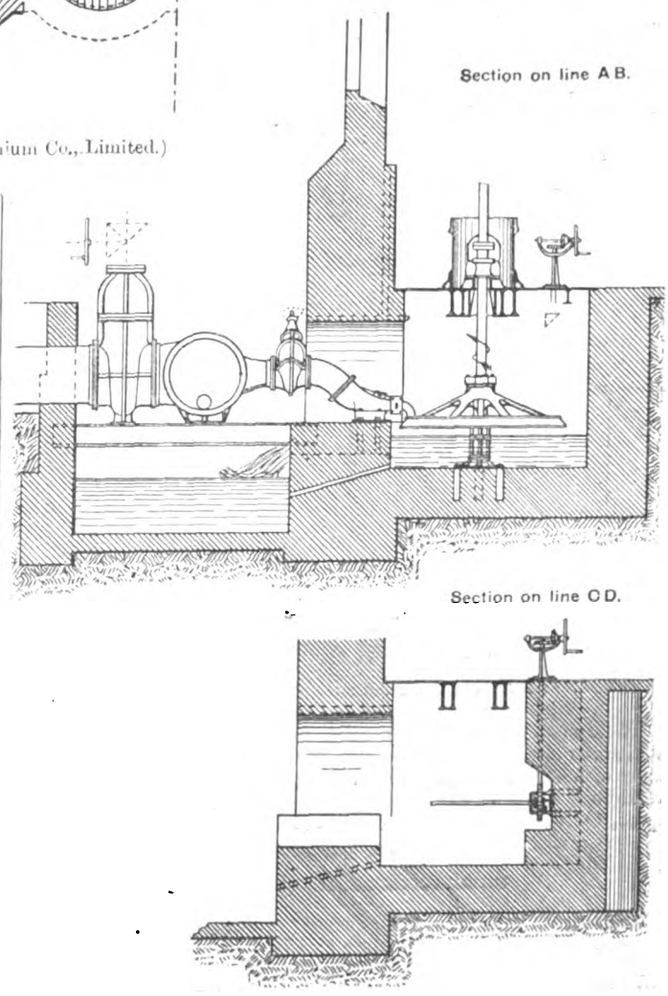

FIG. 3B.—Turbines at the Falls of Foyers, Scotland. (The British Aluminium Co., Limited.)

insufficient. These cases are, unfortunately, of frequent occurrence. On the other hand, if the turbine is constructed to give off the required power under the reduced fall, it must be partially closed for the diminished water supply with the

Digitized by Google

normal fall, whereby the efficiency would be reduced just when it should be highest, if economy is at all the chief object of a turbine plant. The manner in which a high efficiency can be maintained for a diminished water supply is to subdivide the turbine into several compartments, each of which represents a complete turbine. This arrangement has been adopted by Fourneyron for his well-known outward flow turbine, and in the modern *Jonval turbine*. The Fourneyron turbine is provided with a cylindrical gate, which is moved vertically, whereby each compartment is opened or closed. This type has been adopted for the large power plant on the Niagara Falls, but on the European continent they are seldom used. Their efficiency is very good, but, owing to the narrowness of the buckets, they are easily choked.

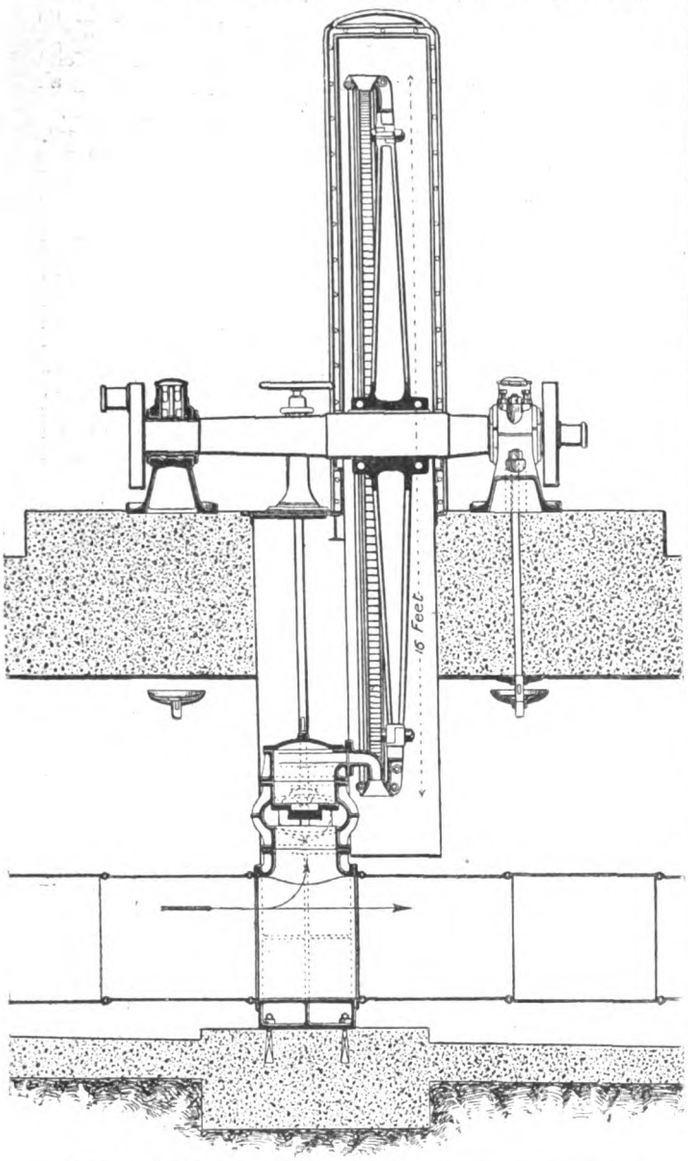

FIG. 4.—Turbines of the Chauxdefonds Waterworks, Switzerland.

The Jonval turbine is a parallel flow turbine, and is, for large variations of the fall and quantity of water, subdivided into two or more concentric compartments. A subdivision in this manner renders it possible to maintain not only the power, but also *the speed*, under a varying fall within very wide limits.

*(To be continued.)*

**ELMORE COMPANIES.**—The financial papers contain communications from shareholders expressing anxiety as to the dividend outlook. In one communication attention is called to the sanguine statement of Mr. W. Elmore, published in October, 1894, as follows :—"The businesses have been cut adrift from wreckers and the shareholders' property and interests made safe. The Companies have practically no trade liabilities beyond the current monthly accounts. They have ample stocks of raw copper, purchased at the bottom of the recently depressed market, and abundance of capital at command to purchase any additional quantities required for the execution of the large volume of orders which the recognised superiority of the product secures."

## THE INTERNATIONAL TELEGRAPHIC CONFERENCE.

The International Telegraphic Conference will be opened at Buda Pesth on June 16th, and as its object and methods are little known outside of telegraph circles, some information on the subject may be interesting. These conferences take place every five years, and have been held in turn in the principal European capitals as follows :—Paris, 1865 ; Vienna, 1868 ; Rome, 1871-72 (at which the cable companies were first represented) ; St. Petersburg, 1875 ; London, 1879 ; Berlin, 1885 ; Paris, 1890. The delegates include representatives of nearly all the Government administrations in the world which work telegraph lines, as well as of all the companies working cables and land lines. The latter are allowed to speak, but not to vote. It is only fair to say, however, that the Government delegates have always shown great consideration for views put forward by the companies' representatives.

The object of the Conference is to draw up from time to time service regulations for the efficient working of international telegraphy, the adjustment of accounts, tariffs, &c. The Director General of Telegraphs of the country in which the Conference is held presides over its deliberations ; and matters of detail, together with the framing of the rules, are delegated to two Commissions, one dealing with all tariff matters and the other with the rules for working. All the decisions of the Commissioners are, however, subject to confirmation by the full Conference.

The chief subjects for discussion at the approaching Conference will probably be the authorised vocabulary lately issued by the International Bureau of Telegraphs at Berne under instructions from the Paris Conference, and the proposal of Germany for a uniform European word rate.

The British representatives to the Buda Pesth Conference are the following :—

| | |
|---|---|
| Post Office ..... | J. C. LAMB, Esq., C.B., C.M.G. |
| Cape Colony..... | H. C. FISCHER, Esq., C.M.G. |
| Natal..... ..... | P. BENTON, Esq., and R. MACKAY, Esq. |
| India ..... ..... | P. LUKE, Esq., and B. T. FFINCH, Esq. |
| New South Wales ... | Sir SAUL SAMUEL, K.C.M.G., C.B., Agent-General. |
| Victoria..... | Hon. DUNCAN GILLIES, Agent-General. |
| South Australia ..... | Hon. T. PLAYFORD, Agent-General. |

The representatives of the Companies are the following :—

The MARQUIS OF TWEEDDALE—
African Direct, Eastern, Black Sea, Europe and Azores, and Eastern Extension Companies.

Lord SACKVILLE A. CECIL—
Eastern, Brazilian Submarine and Pacific and European Companies.

Sir ALBERT A. LEPPOC CAPPEL, K.C.I.E.—
Eastern, Eastern Extension and Brazilian Submarine Companies.

C. W. EARLE, Esq.—
Eastern Extension Company.

J. DENISON PENDER, Esq.—
Eastern, Black Sea, Eastern and South African, Europe and Azores, West African, African Direct, Eastern Extension, Brazilian Submarine and West Coast of America Companies.

M. JULES DESPECHER—
African Direct, Brazilian Submarine, Black Sea, Eastern, Eastern Extension, Eastern and South African and Europe and Azores Companies.

G. DRAPER, Esq.—
Eastern, Black Sea and Eastern and South African Companies.

F. E. HESSE, Esq.—
Eastern Extension Company.

W. HIBBERDINE, Esq.—
Eastern, Black Sea, Eastern and South African, Europe and Azores, Eastern Extension and West African Companies.

W. H. AXWORTHY, Esq.—
African Direct, Brazilian Submarine and Pacific and European Companies.

G. R. NEILSON, Esq.—
Europe and Azores Company.

H. ST. L. SMITH, Esq.—
Eastern, Black Sea, Eastern and South African, Europe and Azores, Eastern Extension and West African Companies.

S. BARBER, Esq., and C. BURT, Esq.—
Anglo-American Company.

GEORGE WARD, Esq.—
Commercial Cable Company.

CH. GERHARDI, Esq., and Senor COROMINA.—
Direct Spanish Company.

E. M. UNDERDOWN, Esq., and O. MOLL, Esq.—
Direct United States Cable Company.

Commodore SUENSON and F. C. C. NIELSEN, Esq.—
Great Northern Telegraph Company.

Digitized by Google

W. ANDREWS, Esq., and F. MOLL, Esq.—
Indo-European Telegraph Company.
R. K. GRAY, Esq., J. JEFFERY, Esq., and W. F. O'BRIEN, Esq.—
Spanish National and South American Telegraph Companies.
Major ALEXANDER WOOD and E. S. HODSON, Esq.—
Western and Brazilian Telegraph Company.
R. T. BROWN, Esq —
West India and Panama Company.
G. VON CHAUVIN, Esq.—
Western Union Telegraph Company.

The Conference will probably last about six weeks, and before separating will fix the place at which the next meeting of the International Telegraph Union will be held. It is not believed that any great changes in international telegraphy will be introduced at Buda Pesth, and the work done will be principally in the direction of simplifying and codifying the existing service regulations.

## PHYSICAL SOCIETY.

At an ordinary meeting of the Physical Society held on May 22, 1896, Prof. Ayrton (Vice-President) in the chair, Mr. R. APPLEYARD read a Paper on

### "Dielectrics."

The author has particularly investigated the effect of temperature on the dielectric resistance. He has employed for this purpose condensers insulated with mica and paraffined paper. In order to eliminate some of the effects of surface leakage, Price's guard-ring arrangement was made use of in all the experiments.

The author finds that the capacity of a paraffin condenser varies irregularly with the temperature, but that to within the accuracy attainable with his instruments (1 per cent.) the capacity of a mica condenser is constant between 33°F. and 110°F. If the resistance of paraffin at a temperature $t$ is represented by $R = R\alpha^t$, the mean value for $\log \alpha$ deduced from all the author's measurements is $\bar{1}{\cdot}96344$. Experiments made with a parallel plate condenser with paraffin as the dielectric show that when the temperature reaches within about 20deg. of the melting point the resistance rapidly falls; when melting commences there is a rapid drop, but while melting is in progress the resistance remains constant.

Prof. AYRTON said he would bear witness to the extreme value of Mr. Price's device, as it completely did away with the necessity for the extreme care previously necessary to prevent errors due to surface leakage. He regretted that he had not had an opportunity of comparing the author's results with those obtained some years ago by Prof. Perry and himself (Prof. Ayrton).

A Paper by Prof. VIRIAMU JONES, on

### "The Magnetic Field Due to an Elliptical Current at a Point in the Plane of the Ellipse and within it,"

was taken as read.

Prof. SILVANUS THOMPSON said that this Paper was of interest, not only on account of the application which others might make of the author's method, but also in that the correction when applied to Prof. Jones's results brought the international ohm more nearly into accord with the true ohm.

Mr. J. J. WALKER said he considered that the Paper was more suited to the Mathematical Society. The integration, which the author reduced to elliptic integrals, might be more easily performed by another method.

Prof. AYRTON said that Prof. Jones's value for the true ohm was now 106·302cm. of mercury.

Mr. CAMPBELL read a Paper on

### "New Instruments for the Direct Measurement of the Frequency of Alternating or Pulsating Electric Currents."

The author employs two arrangements, in one of which a steel wire, the tension on which is variable, and the other a steel spring of variable length clamped at one end, are acted upon by an electromagnet through which the periodic current is passed. The tension or length, as the case may be, is varied till maximum resonance is obtained, a small contact piece being employed to detect when this occurs. The instrument exhibited was capable of measuring the frequency of periodic currents of from 40 to 150 cycles per second.

Mr. WATSON said he thought that in the case of the steel spring there would be a considerable temperature correction, and he suggested a method by which this might be compensated.

Mr. BLAKESLEY asked if the author had found that the spring became magnetised and thus gave the octave.

Mr. TREMLETT CARTER asked whether elastic fatigue influenced the results, and said that a synchronous motor and a speed indicator could be used to measure the frequency.

Prof. SILVANUS THOMPSON suggested that it might be better to employ a polarised apparatus, since to avoid the impression of forced vibrations on the spring it was better, as was done in the case of tuning forks, to make it massive. It had been found in other cases, such as in Hughes's telegraph and the telephone, that better results were obtained with polarised apparatus. He (Prof. Thompson) had used a telephone, placed anywhere near a magnet traversed by the periodic current, together with a tuning fork, which gave beats with the note produced by the telephone, to measure frequencies. The variations in frequency ordinarily met with in practice were much greater than was generally suspected.

Mr. BLAKESLEY said he considered that the advantage of the author's instrument over a telephone and tuning fork was that it was continuously variable over a large range.

Mr. ENRIGHT asked if the author had been troubled by the spring or wire breaking into overtones. In some experiments, in which rather long wires were used, he had been troubled in this way.

Prof. AYRTON said that he did not think that it was possible to get the wire or spring to respond to the octave unless the alternating current contained a component of the frequency of the octave. In fact he had himself used such a stretched string as a wave analyser. He had used a telephone to prove that the note given by a hissing alternate-current arc corresponded in frequency to that of the current. In the instrument used by Prof. Perry and himself a polarised arrangement was always employed, since the alternating current was passed either through a wire in a constant magnetic field, or through an electromagnet which acted on a wire through which a constant current was passed.

The AUTHOR, in his reply, said that the instrument responded, though feebly, to the octave, and this response might be made use of to check the accuracy of the scale.

The Society then adjourned till June 12th.

## LEGAL INTELLIGENCE.

### County of London and Brush Provincial Electric Lighting Company (Limited) v. Vestry of St. Leonard, Shoreditch.

An action has been commenced by the County of London and Brush Provincial Company to restrain the Vestry of St. Leonard, Shoreditch from laying down electric lines beyond the area within which the Vestry are authorised to supply energy under the Shoreditch Electric Lighting Order, 1892. It appeared from an affidavit that the Vestry commenced on May 21st to excavate a trench for the purpose of laying down electric lines within the parish of St. Luke, Middlesex, a district for which the County of London Company have a Provisional Order. On the application of Lord Robert Cecil (instructed by Mr. Sydney Morse) Mr. Justice Henn Collins on the 21st inst. gave the Company leave to serve summons with writ for June 2nd, and granted an injunction in the meantime.

## TRADE NOTES AND NOTICES.

*[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]*

### NEW BOOKS AND EDITIONS.

*The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. The NEW EDITION is NOW READY. Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

TENDERS INVITED.—The Corporation of Leeds require tenders for an electrical installation sufficient for working by the over head system a double track of tramway seven miles in length. The work is divided into seven contracts, details of which will be found in our advertisement columns. Tenders have to be sent in to the Town Clerk, Town Hall, Leeds, not later than June 20th, and particulars, plans, &c., can be obtained from the City Engineer, Municipal Buildings, Leeds, or from Dr. John Hopkinson, F.R.S., 5, Victoria-street, Westminster, London, S.W.

——— The Caledonian Railway Company invite tenders for stores for 12 months from August 1st next. These include telegraph and electric appliances, india-rubber, copper rivets, crucibles, galvanised wire, tools, &c. Specifications and forms of tender may be obtained on and after Monday next from the Superintendent of Stores, Mr. Jas. Lorimer, Charles-street, St. Rollox, Glasgow, and tenders must be sent in to the Secretary (Mr. J. Blackburn), 302, Buchanan-street, Glasgow, by Monday, June 15th.

Digitized by Google

TENDERS INVITED.—The North Eastern Railway Company require tenders for telegraph apparatus, wires and line stores, for six months. Tenders to the Secretary, York, by June 8th.

——— Tenders are required for the installation of the electric light at the Devon and Exeter Hospital. Tenders to Mr. C. Cole, 50, High-street, Exeter, by June 3rd.

——— The Cork Corporation invite tenders for providing and erecting the necessary plant and apparatus for the electric lighting of the municipal pumping station. Tenders to Mr. D. F. Gilinan, Municipal-buildings, Cork, by June 3rd.

——— The Municipal Authorities of Mako, Hungary, require tenders for the electric lighting of the town.

——— The Municipal Authorities of Nava del Rey (Valladolid), Ronda (Granada), and Torre Vieja (Alicante), Spain, are inviting tenders for electric lighting concessions; in the first and last cases for a period of 20 years. Tenders in each case to El Secretario del Ayuntamiento.

——— The State Small Arms Authorities at Spandau require tenders for the supply of 900 incandescent lamps. Tenders to the Königliche Direktion der Gewehr fabrik, Spandau, Germany, by June 17th.

TENDERS ACCEPTED.—The Brighton Corporation have accepted the tender of the Callender Company for the supply of armoured and unarmoured lead-covered electric light cables for the year ending May 1, 1897.

——— The Forfar Corporation have accepted the National Telephone Company's tender for fitting up fire alarms, &c., for £23. 8s.

TENDERS RECEIVED.—The Bray Town Commissioners received 30 tenders for the supply of additional machinery at the electricity works. These are being considered by a special committee.

SALE BY AUCTION.—Particulars will be found in our advertisement columns of the disposal by public auction by Messrs. Wheatley Kirk, Price and Goulty, on Tuesday, June 2nd next, of the entire contents of the late lighting station of the Reading Electric Supply Company (Limited), situated in Thorn-lane, Duke-street, Reading, Berks. The sale of this plant, &c., is taking place owing to the Company having completed their new central station. It will be seen that the sale includes two Babcock-Wilcox boilers, steam engines by Browett and Lindley, Alley and Maclellan, and Greenwood and Batley; Thomson-Houston dynamos, and a quantity of useful electric plant and apparatus, instruments, &c. Catalogues can be obtained from the auctioneers, or direct from the Reading Company.

APPOINTMENT.—The Electric Lighting Committee of the Blackpool Town Council have decided to appoint Mr. Quinn borough electrical engineer, at a salary of £300 per annum, in succession to Mr. Hesketh, who was recently selected to fill the position of electrical engineer to the Queensland Government. Mr. Quinn has been engaged as chief assistant engineer at the Brighton Corporation Electricity Works for the past five years. Mr. A. T. Cooper will continue to act as assistant at Blackpool.

APPOINTMENTS VACANT.—The Corporation of Lincoln, who intend to establish electricity supply works, invite applications for the position of electrical engineer. Salary £300 per annum. Applications must be sent in to Mr. H. K. Hebb, Clerk to the Urban Sanitary Authority and Deputy Town Clerk, by Saturday, June 6th. Some additional particulars are given in our advertisement columns.

——— A principal is required for the new technical schools at Swindon. Commencing salary £250 per annum. Applications to the Swindon and North Wilts Technical Education Committee, Technical Schools, Swindon.

REMOVAL.—Messrs. Eugen Conrady and Co. inform us that they have removed their works and offices from Keighley to 35, Charles-street, Hatton-garden, London, E.C.

WORKS EXTENSION.—The Brush Electrical Engineering Company have decided, in consequence of the active demand for the "Raworth" universal steam engine, to considerably extend their works at Loughborough. The new tool shop, which will be exclusively devoted to the engine trade, is to be 160ft. long by 48ft. wide. Building operations have already been commenced, and will be pushed forward with all despatch, so as to avoid delay in execution of orders.

BANKRUPTCY.—The examination of C. G. Stewart, jun., electrician, takes place at the Court House, Edinburgh, on June 8th.

LIQUIDATIONS.—At a meeting of the United Gutta Percha and Rubber Company (Limited) on April 30th it was decided to wind up the Company voluntarily. The decision was confirmed on May 19th, when Mr. D. S. Carson, 209, West George-street, Glasgow, was appointed liquidator. All claims must reach the liquidator by July 6th.

LIQUIDATIONS.—A meeting will be held at 30, Moorgate-street, E.C., on June 30th, at 3 p.m., to receive an account of the winding-up of the District Messenger Company of Paris (Limited).

——— At a meeting of the proprietors of the British Thomson-Houston (Limited) on the 1st inst., it was resolved that, for the purposes of reconstruction, it was advisable to wind up the company voluntarily. This resolution was confirmed on the 18th inst., and Mr. J. Devonshire, 38, Parliament-street, Westminster, S.W., was appointed liquidator. Particulars of the registration of the new Company are given in another column.

——— A meeting is to be held at the office of Mr. R. Innes, 10, Norfolk-street, Manchester, on June 23rd, at 3 p.m., to receive an account of the winding-up of Hargreaves and Shaw (Limited), electrical and mechanical engineers.

WOODHOUSE AND RAWSON UNITED, LIMITED (IN LIQUIDATION).—A sequel to the meeting of the principal trade creditors in this concern, which was held on April 21st, and particulars of which were given in our issue of the 24th ult., comes in the form of a circular issued by Messrs. Pilling and Co., chartered accountants, of 2, Clarence-buildings, Booth-street, Manchester, inviting those of the creditors who are disposed to authorise the Official Receiver and Liquidator of the Company to tender for the interest of the debenture holders and debenture-stock holders in moneys alleged to be recoverable from the Directors and officers of the Company, which are now offered for sale under an order of the Court, to send in their names with the amount they are prepared to subscribe towards the venture—we had almost written gamble. The position is certainly a most peculiar one. Counsel has advised that there are certain sums clearly recoverable from the persons referred to, and the First and Second Debenture holders and others have been asked to subscribe the necessary funds to indemnify the Official Receiver from all liability in taking action in the matter. It has now come to the turn of the trade creditors to have this offer placed before them, and it remains to be seen whether this body will feel more disposed than others who have been approached to take steps to bring the Directors and other officials before the Courts. The unsecured creditors' claims amount to about £15,000, and the committee appointed by the creditors to consider the matter suggest that an all-round contribution should be made of 10 per cent. of the creditors' claims, which, it is considered, would provide sufficient funds to contest the points raised by counsel's opinion.

CABLE-MAKING MACHINERY.—Messrs. Johnson and Phillips remind us that in August last when their special catalogue of cable-making and wire-covering machinery was issued, it was foreshadowed that an important and comprehensive addition would shortly be made to it. This department of the firm's business has, however, been too busily employed to give attention to the matter, and those interested are therefore informed that a number of illustrated sheets giving particulars of some of the machines manufactured since the catalogue was published can now be obtained. The list of special machines made shows about 20 different kinds of which full particulars can be obtained on application. As Messrs. Johnson and Phillips are not only makers of these machines but are also users, purchasers have the great advantage of the experience gained in the development of the machines for practical use.

EXPORTS OF ELECTRICAL APPARATUS AND MATERIAL.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from May 20th to May 27th, with the ports of destination:—

*Australasia*—Albany, £2,108 (including £1,310 telegraph material); Fremantle, £257 (including £180 telegraph material); Launceston, £131 (including £56 electric lighting apparatus); Melbourne, £624 (including £201 telegraph material); Rockhampton, £80 (electric lighting apparatus); Sydney, £123; Wellington, £216. *Brazil*—Rio de Janeiro, £5,285 (telegraph material). *Burma*—Rangoon, £31. *Canada*—Montreal, £30. *Ceylon*—Colombo, £25 (telephone). *Chile*—Valparaiso, £1,010 telegraph material). *China*—Shanghai, £9,436 (including £9,434 telegraph material). *Egypt*—Alexandria, £135 (telegraph material); Port Said, £7. *France*—Boulogne, £33. *Germany*—Borkum, £2,199 (telegraph cable). *Holland*—Amsterdam, £80; Flushing, £32. *Hong Kong*—£39 (telephone stores). *India*—Bombay, £213 (including £42 telegraph material); Calcutta, £92. *Japan*—Yokohama, £221. *Malta*—£62 (telegraph material). *North Borneo*—Labuan, £17 (telegraph apparatus). *Russia*—Odessa, £465 (including £436 telegraph material); St. Petersburg, £93. *South Africa*—Cape Town, £39; Delagoa Bay, £66 (telegraph material); Durban, £30; East London, £513; Lourenco Marques, £73 (telegraph material); Port Elizabeth, £31. *Straits Settlements*—Singapore, £267. *Sweden*—Gothenburg, £44 (telegraph material); Stockholm, £164 (telegraph material).

MACHINERY CATALOGUE.—A useful list reaches us from Messrs. John Turner and Sons, electrical engineers, of Denton, near Manchester, whose London agency has just been placed in the hands of Mr. C. F. Quicke, M.I.E.E., of 72, Finsbury-pavement, E.C. The list is illustrated and contains full particulars of dynamos, motors, and coupled plants, manufactured at Denton. Several of the

Digitized by Google

machines are specially constructed for different classes of work. The apparatus described includes main and standard switchboards and switches, and on page 26 a useful type of motor fan, which is claimed to be a most efficient ventilator for ships, public buildings, &c., and is built in a variety of sizes. In addition to the construction of machinery and apparatus, Messrs. Turner and Sons undertake the carrying out of complete light and power transmission installations, and stock various kinds of arc and incandescent lamps, cables, and wires, measuring instruments, &c. The catalogue contains a brief account of the Denton works, which were established 36 years ago, and of the firm's works at Danbury, Conn., U.S.A., which, though more recently established than the English factory, are equipped up to the high standard of excellence which the American market demands. The management on both sides is identical, and the Danbury works being situated within easy reach of New York and Boston, facilities for handling large contracts are at the firm's command.——The Blymyer Ironworks Company, of Cincinnatti, U.S.A., forward us a handsome catalogue of machinery chiefly designed for sugar cane, coffee, and rice plantation work. Included in the catalogue are particulars of the portable and stationary steam engines, boilers and fittings, waterwheels, &c., manufactured by the Company.

"Electric Wiring."—We have received from the General Electric Company, of Queen Victoria-street, London, a reprint in pamphlet form of the Paper on "Electric Wiring" read by Mr. F. Bathurst before the Institution in November last, together with Mr. Bathurst's reply to the discussion upon the Paper. The discussion itself is omitted. Copies can be obtained from the General Electric Company on application.

Guide Book.—The Immisch Electric Launch Company (Limited) have just issued a handy little guide to the Thames valley, entitled "Electric Launches on the Thames." The book contains, among other things, a calendar of river fixtures, railway time tables for the summer months, a descriptive guide to the Thames between Richmond and Oxford, two or three maps, and plenty of information about electric launches.

Scotland.—Those contemplating a journey to the Highlands are certainly well provided with literature. We have previously referred to two popular guides issued with the object of meeting the demand for information on this subject, and now have to acknowledge the receipt of a useful handbook issued by the Aberdeen Steam Navigation Company, of London and Aberdeen, which takes the tourist from London Bridge to the Highlands and back, describing the scenery and points of interest *en route*.

---

Amazon Cable.—A number of additional telegraph offices have just been opened in the Amazon cable districts, including Cametá, Chaves, Breves, Itacatiara, Macapá, Monte Alegre, Monsquiers, Obidos, Parintins, Pinheiros and Souré.

Asylum Lighting.—The Cheshire County Council have decided to introduce the electric light into the Upton Lunatic Asylum at an estimated cost of £3,000.

Bath.—At a special meeting of the Urban Sanitary Authority on Friday it was decided to borrow £45,000 for the purchase of the City of Bath Company's undertaking and for providing capital for extensions of the plant and mains.

Birmingham.—The National Telephone Company are fitting up a very complete system of telephonic communication at the new General Hospital. The arrangements will comprise a miniature telephone exchange. A switchboard will be fitted up in the porter's office, from which wires radiate to sixty-one different parts of the building, and communication can be effected between any part of the hospital and the porter's inquiry office. An electrical annunciator will be erected at the entrance lodge, to enable indication to be made of the presence in the building of any particular doctor or nurse.

Bury.—The Bury, Rochdale and Oldham Tramway Company have asked the permission of the Bury Town Council to the introduction of the overhead system of electric traction on their lines, and for the terms upon which they would supply the necessary electrical energy for working the trams.

Chelmsford.—The Town Council have decided that, in view of the considerable expenditure on other public works, the question of the purchase of the Chelmsford Electric Light Company's undertaking must stand over for the present.

Cheltenham.—The Town Council have received sanction to borrow £23,430 for electric light extension purposes. Application was made for £25,000, but the Local Government Board have declined to sanction the loan of £70 for a proposed extension outside the lighting area, and an item of £1,500 has been held in suspense for further particulars.

Coventry.—From the quarterly statement just presented by the Electric Light Committee it appears that 10,642 units were sold during the three months ending March 31st, and the total income for this period amounted to £284. 1s.

Country House Lighting.—Cairnbulg Castle, near Fraserburgh, is to be fitted up for the electric light.

Dover.—Councillor Fry, who is endeavouring to get the Town Council to establish electric tramways in Dover, has succeeded in inducing the Council to appoint a deputation to visit Rouen or Hamburg for the purpose of inspecting the system of electric traction employed in those towns and of collecting information. In the course of a lengthy speech he gave details of a scheme which included the construction of tramway lines from the pier to Folkestone-road, Maxton and Buckland, to be worked on the overhead system.

Edinburgh.—On Tuesday last the Town Council formally approved the recommendation of the Electric Light Committee to reduce as from the 15th inst. the price of electric energy from 6d. to 5d. per unit, the charge for each arc lamp to £18 per annum, and to abolish meter rents. Mr. Mackenzie, in support of the recommendation, said their station was opened on April 11, 1895, with 48 customers and with an equivalent of 2,000 8 c.p. lamps connected, and after 13 months' working they had 425 customers representing 54,360 8 c.p. lamps, and including the arc lamps the total was 58,860 8 c.p. It was thought that the original plant, which was designed to supply 40,000 8 c.p. would meet their requirements for two or three years, but so great was the demand that at Christmas, 1895, every engine and boiler in the station was fully loaded, and in order to avoid a breakdown they were compelled to borrow an engine from one of the London companies, the demand having come on so suddenly that there was no time to get one of their own. In order to cope with the increased demand during next winter they had ordered five boilers, six low-tension machines of 360 H.P. each, a number of high-tension machines and other plant, which would be ready to run at the end of September, thus more than doubling the capacity of the station. The necessary extensions of the mains were being carried out, and new consumers were being connected daily. The condition of the undertaking was very promising, not only from the engineering and demand points of view, but last year's financial results and the current year's prospects were equally good. For the first five and a half months the station was being worked at a loss, but by the end of last September the position had so improved that the income just balanced expenditure. From September, 1895, to the middle of April they were working at a profit, but during the last two months the load was very light, and the station was again being operated at a loss. The total income from private lighting for the 13 months of their existence was £13,220. 18s., and from public lighting £3,604. They had supplied 550,000 units to private consumers, and 320,000 units for public lighting, a total of 870,000 units, representing an income of £16,824. The station expenses, including carbons, trimming arc lamps, and upkeep of mains, amounted to £4,700, and the standing charges, interest, and sinking fund to about £8,100, making a total of £12,800, leaving a profit balance of about £4,024. Mr. Mackenzie thought this was a highly satisfactory condition of affairs, and he claimed it as a "record" for a first year's working. Reckoning the price of the current at 6d. per unit, the engineer had estimated the income for the present year at £28,100, and the expenditure at £21,122, leaving a balance of £6,978. The Committee, however, had decided that it would be advisable to reduce the charge for current, and had, therefore, fixed the charge to private consumers at 5d. per unit, and the charge for current for motors, &c., at 3d. Owing to these changes, the abolition of meter rents and the reduction in the charge for arc lamps, the estimated revenue would be reduced by about £4,100, leaving an anticipated balance of £2,878. Mr. Mackenzie referred in eulogistic terms to the services rendered by their consulting engineer (Prof. A. B. W. Kennedy), and their late resident engineer (Mr. E. W. Monkhouse), and, in conclusion, said it was his intention to give notice of motion to establish a depreciation fund. The report was unanimously adopted.

Electricity in Mining.—In our issue of March 27th we referred to a statement made by the Directors of the Moodie's Fortuna Mining Company, that the work of crushing by electric power at the mine had not proved successful. This statement was challenged at the time by Mr. W. B. Esson and Mr. H. K. Baynes; and now Mr. H. J. S. Heather, the electrical engineer in charge at Moodie's electrical works, Barberton, in a communication to the *Financial News*, further contests the point, and says:—

"In your issue of March 24th there appeared an article which has exercised the minds of many with regard to the application of electricity to mining, the statement having been made that attempts to crush by electric power at Moodie's Fortuna have not been a success. If this were so, does it not appear strange that the United Ivy Reef, who have been dependent on power supplied from the same installation, have found it a success, and with it have been able to declare a dividend, though crushing ore of no greater value? The fact is that the power is a success; but it would appear that the management of the Fortuna mill has not been; for we were asked by them to shut down a considerable number of times, owing to something or other going wrong with the battery. Would anyone say that Fraser and Chalmers' mills are not a success because

Digitized by Google

one of them has had to shut down so often? We have frequently had to complain of the stonebreaker being started when filled with stone, and being put on and off without the arranged signals being given. If, moreover, the power were not a success, how came it that no complaint was ever made to me on the many occasions of my visiting the mill? I never heard any, and I am authorised by the manager of Moodie's Company to say that he received none from the manager of the Fortuna. As to the attempts to crush by means of the power, I have to point out that these attempts succeeded in using up all the available ore. With regard to the installation itself, I must admit that Moodie's Company have not for use as much power as could be obtained from the same source under a different system. It has been arranged to make the necessary modifications, and the requisite material has been ordered, and will, on arrival, be erected without delay. Meantime, all those who have contracted to take power from the Company are being supplied according to their requirements."

ELECTRIC TRAMWAYS IN WEST AUSTRALIA.—In the interim report recently issued by the Directors of the Town Properties of West Australia (Limited) reference is made to the necessity for tramways, and it is stated that a scheme for the construction and equipment of a system of electric tramways is being formulated by Sir Douglas Fox. An electrical engineer has been despatched to the colony for the purpose of collecting information.

ESTON.—A committee of the whole Council are considering the question of establishing electric light works in this town.

FLEETWOOD.—The Urban District Council have decided to transfer their Provisional Order to Messrs. Bennett and Druce.

FOLKESTONE.—After a lengthy discussion the Town Council have decided to dispose of their Provisional Electric Lighting Order to Mr. W. B. Hopkins, of Parliament-street, Westminster.

GLASGOW.—The deputation which recently visited Portsmouth, Blackpool, and Brighton for the purpose of examining and reporting upon the systems of electric lighting in these towns, have presented a report, which states that "for the purpose of giving the most effective illumination, and diffusing the light over the largest area without shadows, the overhanging lamp adopted at Brighton is the best," and recommends its adoption in Glasgow.

HAMPSTEAD.—The Electric Lighting Committee presented their accounts from the inauguration of the electricity station in October, 1894, to December, 1895, at yesterday's meeting of the Vestry. The total capital expenditure at the end of December last amounted to £56,552; the total revenue was £4,606. 8s. 7d. (including £3,432. 5s. 9d. from private lighting); expenses amounted to £5,608. 17s. 9d. (£2,035. 16s. 9d. for coal, £947. 15s. for wages and £1,114. 17s. 7d. for management expenses), and interest and sinking fund charges came to £1,934. 19s. 3d., leaving a net deficit of £2,916. 5s. 3d. The number of units sold was 177,300.

HASTINGS.—The contract with the Hastings and St. Leonards-on-Sea Electric Light Company for lighting the sea front expires on July 1st, and as the Company had expressed their intention of not renewing, except at a much higher figure per lamp than is now paid (£25), the Public Lighting Committee have discussed the question of putting down an independent generating plant. Mr. P. H. Palmer, the Borough Engineer, has prepared a report on the matter, recommending the Town Council to undertake their own street lighting, and to carry out the terms of the Hastings Provisional Order (1890). The old pumping station in Waterworks-road is given as a site for the generating station, and the Council are recommended to put down plant capable not only of supplying current to the present arc lamps, but also of lighting the Town Hall, Brassey Institute, and other public buildings. Mr. Palmer puts the cost of equipping the station with duplicate machinery and buying the Company's arc lighting plant at £7,560. The scheme has been submitted to Mr. P. M. Grenville, electrical engineer, of Old Queen-street, London, who has reported favourably on the proposals. The estimated cost of running 50 arc lamps, including interest, sinking fund, &c., was put at £1,639, or £32. 15s. 7d. per lamp per annum. The Company's figures represented £35 per lamp per annum if current were supplied till 11:30 p.m., or £47 if supplied all night. The Committee therefore recommended that the Council's scheme be proceeded with, and that application be made to borrow £7,560 for the purpose. These recommendations have been adopted.

KINGSTON-ON-THAMES.—From the last statement of the Electric Light Committee it appears that the department continues to make steady progress. The revenue from private customers has increased from £1,116 in 1894 to £1,617; 66,000 units were supplied to the public lamps at 2½d. per unit. The net result is a deficit of £1,283 on the year's working. Arrangements have been made for charging electric launches during the summer months, and the Committee anticipate a good demand for energy for this purpose. Various extensions of the mains were ordered to be carried out at the last meeting of the Council. Negociations for the extension to the Coombe and Malden districts are still in progress.

MILL LIGHTING.—Messrs. Humphries and Bobbett's new flour mill, Castle-street, Bristol, is to be lighted electrically.

POLICE.—At the Marlborough-street Police Court on Wednesday a journalist named MacLeod was charged with obtaining credit to the extent of £35. 10s. from Mr. R. Aylmer, of 47, Victoria-street, Westminster, without informing him that he was an undischarged bankrupt. The prosecutor was slightly acquainted with the prisoner, and received an order from him for installing the electric light at a house in Jermyn-street. The work was duly executed, but payment had not yet been made. As the result of inquiries it was found that the defendant was an undischarged bankrupt and therefore these proceedings were taken. For the defence it was stated that the order was given on account of the committee of a club which was being promoted, and MacLeod was prepared to pay the money immediately. The defendant was remanded for a week in two sureties of £25 each.

PORTSMOUTH.—The accounts for the first year's working of the electricity works to March 31st last have been published, and are of a satisfactory character. The revenue amounted to £7,387, and the expenses, to £4,010, leaving a gross profit of £3,377. £3,330 has been applied towards the payment of interest and sinking fund (which together absorb £3,749), so that the net deficiency only amounted to £419. During the last quarter of the period under review the station was being operated at a profit, and as numerous extensions of the mains are being made the Electric Lighting Committee anticipate being able to present an even more favourable balance sheet at the end of the present year.——In order to create a demand for current for lighting places of worship on Sunday the City Council are advised to advance the funds for wiring and fitting up the buildings at 5 per cent., the capital to be repaid by quarterly instalments.

POSTAL TELEGRAPH CLERKS.—The annual conference of the Postal Telegraph Clerks' Association is now being held at Exeter. The proceedings commenced last evening.

PRESENTATION.—Mr. John Hesketh was at Blackpool last week presented with two illuminated addresses, one by the members of the Electric Lighting Committee of the Blackpool Corporation (including the Mayor), and one by the staff at the station. The former address sets out the esteem in which Mr. Hesketh is held by the Committee, and points to the satisfactory progress of the electric lighting under Mr. Hesketh's management.

SHOREDITCH (LONDON).—The National Telephone Company have agreed to pay half the cost of opening and closing the trenches where the telephone lines are put down side by side with the electric light cables in this district, have further agreed to pay a yearly sum of 1s. per pipe per 100 yards for wayleave, and to put the Vestry upon the telephone exchange free of charge. A formal contract has, we understand, been entered into upon these terms and conditions.

WREXHAM.—As the Board of Trade have revoked the Provisional Order of the Wrexham Electric Light and Power Company, the Lighting Committee of the Town Council are considering the question of the establishment of electricity supply works.

## COMPANIES' MEETINGS AND REPORTS.

### West Coast of America Telegraph Company (Limited).

The report of the Directors of this Company for the year ended December 31st last, to be presented at the meeting to be held at Winchester House, London, E.C. to day (Friday), states that the gross income for the year 1895 was £32,930. 5s. 9d., against £21,753. 12s. 2d. in 1894. The traffic receipts were adversely affected by the stagnation in the nitrate industry, and other local causes; but, owing to a readjustment of the proportions of the international traffic receipts for the year, the income of the Company was sufficient to pay the expenses and the interest on the debentures. The total expenses were £20,930. 5s. 9d., against £20,154. 4s. 11d. in 1894. The Company's repairing steamer "Retriever" has been fitted with a new steel main boiler, the cost of which, £1,978. 0s. 3d., has been charged to the reserve fund. The steamer is now in first-class condition. The Company's cables and land lines are maintained in good working order. Mr. J. Denison Pender and Mr. Frederick Walters both offer themselves for re-relection as Directors, and Mr. John Francis Clarke (the auditor) also seeks re-election at the meeting.

### Bournemouth and District Electric Supply Company (Limited).

The following is the report of the Directors for the year 1895, to be presented at the meeting to be held at Bournemouth, on Tuesday next:—

The capital account shows an expenditure of £20,845. 8s. 7d., chiefly upon buildings, machinery, and mains, the funds for which were borrowed from the County of London and Brush Provincial Company. Notwithstanding the reduction in the price of current from 8d. to 7d. per unit, made in April, 1895, the total income amounted to £7,431. 3s. 10d., an increase of £458. 13s. 8d. over 1894, and the expenditure to £5,272. 12s. 7d., a reduction of £57. 15s. 10d. The gross profit amounted to £2,153. 11s. 3d., compared with £1,642. 1s. 9d. in 1894; but owing to increased charges

Digitized by Google

for interest on sums borrowed for capital expenditure, there is a debit balance of £237. 15s. 9d. to be carried forward. On December 31st last there was an equivalent of 20,978 8 c.p. lamps, connected to the Company's mains, an increase of 1,798 lamps, or 9½ per cent. During the period under review, 243,816 units of current were sold, against 214,374 in 1894, an increase of nearly 14 per cent., whilst the total cost per unit was reduced from 5·91d. to 5·19d. The generating station has been rebuilt and rearranged during the past year, and, with the advantage of the many improvements which have been adopted, the Directors anticipate a considerable further reduction in cost of generation during the present year.

## Southampton Electric Light and Power Company (Limited).

The Directors' report to the meeting of shareholders, to be held on June 1st states that the business of the Company for the year 1895 steadily increased, and after paying interest on loans and debentures and debiting Directors' fees and writing off preliminary expenses, there is a net profit, including the £35. 14s. 1d. brought forward, of £94. 14s. 9d. The revenue and expenses from 1891 are as follows :—

| | Lamps (equiv. 8 c.p.) | Units sold. | Revenue. £ s. d. | Expenses. £ s. d. |
|---|---|---|---|---|
| 1891 (part only) | ... ... | 5,469 ... | 350 5 11 ... | 535 2 1 |
| 1892 ..... | 2,200 ... | 35,537 .. | 1,153 4 10 ... | 1,152 0 4 |
| 1893 ..... | 3,162 ... | 53,848 ... | 1,606 14 8 ... | 1,121 4 8 |
| 1894 ..... | 5,396 ... | 85,501 ... | 2,491 6 7 ... | 1,676 14 4 |
| 1895 ..... | 6,887 ... | 100,473 ... | 2,862 6 1 ... | 1,895 10 8 |

A Provisional Contract has been signed for the sale of the Company's undertaking to the Southampton Corporation for the sum of £21,000. No dividend is to be paid out of the profits of 1895, but the "Preliminary Expenses" item is to be written off. Formal resolutions for the winding-up of the Company and the distribution of the assets will be submitted to the meeting.

## NEW COMPANIES, STATUTORY RETURNS, &c.

**BRITISH THOMSON-HOUSTON (LIMITED)**.—This Company was registered on May 18th with a nominal capital of £240,000 in 4,000 "A" and 20,000 "B" shares of £10 each, to carry into effect an agreement with the liquidator of the British Thomson-Houston (Limited), in liquidation, to construct, repair, maintain and run installations, wires, cables, and other works for the supply and distribution of electricity for lighting, heating or motive power purposes, and for working by electricity any railways, tramways, or other works, to work, maintain and carry on electric railways or tramways, telegraphic or electric light systems, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and manufacturers of and dealers in all apparatus required for or capable of being used in connection with the generation, distribution, supply, accumulation and utilisation of electricity. The subscribers with one share each are C. Burrell, banker ; E. Lazarus, bank manager ; W. A. McArthur, colonial merchant ; J. T. Merz, chemical manufacturer, T. T. Thompson, merchant ; E. Thurnauer, engineer, and H. Lee, accountant.

**LONDON ELECTRIC OMNIBUS COMPANY (LIMITED)**.—This Company was registered on May 18th with a capital of £250,000 in £1 shares, to carry into effect agreements with Radcliffe Ward and the Solar Accumulator Company, and to carry on the business of an electric omnibus company in all or any of its branches, electricians, electrical and mechanical engineers, suppliers of electricity, manufacturers of electrical apparatus, coach, omnibus and carriage builders, &c.

**MANCHESTER ELECTRICAL WORKS (LIMITED)**.—This Company was registered on May 18th with a nominal capital of £1,000 in £1 shares, to carry on business as manufacturers of and dealers in electrical, telegraphic and scientific instruments, contractors for the sale, erection and maintenance of, and dealers in and suppliers of electrical engineering apparatus, electrical and mechanical engineers, and to carry on the business of an electric light company in all or any of its branches. The first subscribers with one share each are W. Pirrie, W. Brown, F. C. Sanders, A. W. Smedmore, F. G. Phillips, F. Weeks, and F. Johnson.

**COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY (LIMITED)**.—The annual return to May 6th has been filed. The nominal capital is £800,000, in 40,000 Preference and 40,000 Ordinary shares of £10 each ; 10,000 of the former and 22,475 of the latter have been taken up, and the full amount called ; £324,346 has been paid.

**EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED)**.—The annual return of this Company, made up to May 13th, has been filed. Out of a nominal capital of £3,000,000, in £10 shares, 250,000 have been subscribed for, the full amount called, and £2,500,000 received.

**EDISON-GOWER-BELL TELEPHONE COMPANY OF EUROPE (LIMITED)**.—The annual return of the above-named Company, made up to April 9th, has been filed. The nominal capital is £500,000, in £1 shares, of which 385,009 have been taken up. 370,000 of these have been issued as fully paid, and the full amount has been called on the remainder.

**SCOTTISH HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED)**.—The annual return of this Company, made up to April 30th, has been filed. The capital of £100,000 is divided into 19,900 Ordinary shares of £5 each and 100 Founders' shares of similar value ; 730 of the former and all of the latter have been taken up, and the full amount per share has been called ; £4,258 has been received, and £162 is still in arrears. The sum of £108 has been received in respect of 54 forfeited shares.

## CITY NOTES.

**MEMORANDA**.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 31½d. per oz. (May 28th). Consols (2¾ per cent.) 113¼—113½ for money, 113¼—113½ for account ; 2½ per cent. 106¼—106¾ (May 28th). Stock Exchange Settling Days : Consols, June 1st ; Stocks and Shares Continuation Day, June 10th ; Ticket Day, June 11th ; Pay Days, May 29th and June 12th ; Mining Share Carry-over Day, June 9th.

**CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED)**.—The traffic returns of this Company for the week ended May 24th were £893, against £884 in the corresponding week of 1895, an increase of £9. The total receipts for the half-year amount to £19,693, against £19,604 for the corresponding period of 1895, an increase of £89.

**CONTINENTAL METROPOLITAN TRAMWAYS COMPANY (LIMITED)**.—The Directors of this Company announce that they are in negotiation with a French syndicate for the sale of their Paris undertaking.

**JAMES HICKS AND SON (LIMITED)**.—At the recent annual general meeting of this Company (gas, &c., lamp manufacturers, Birmingham), the Chairman, in the course of his speech, stated that they had suffered severely from the competition of the electric light, as the best class of their customers were those who were ready to adopt electric lighting.

**LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED)**.—The Directors of this Company have issued a Circular to their shareholders, stating that the Act of Parliament confirming the sale of their undertaking to the Corporation has received the Royal assent, and that the actual transfer will take place on July 1st next, on which date the Directors propose to pay £8. 5s. per share, being £8 2s. in respect of capital and 3s. for dividend at the rate of 6 per cent. for the half-year to July 1st.

**LIVERPOOL OVERHEAD RAILWAY COMPANY**.—The traffic receipts of this railway for the week ended 24th inst. amounted to £1,178. The amount for the corresponding week last year was £1,135 ; increase, £43.

**LONDON ELECTRIC OMNIBUS COMPANY (LIMITED)**.—Letters of allotment have, it is stated, been posted for the recent issue of capital in this Company.

**MIDDLESBOROUGH ELECTRIC LIGHT, HEAT AND POWER COMPANY (LIMITED)**.—The condition of this Company, the capital of which is chiefly held in this country, is stated to show steady improvement.

**REUTER'S TELEGRAM COMPANY (LIMITED)**.—The annual general meeting of this Company was held at the offices, Old Jewry, E.C., on Wednesday, the Chairman (Admiral Sir J. C. D. Hay) presiding. In moving the adoption of the report and accounts, the Chairman said that though the Company's prospects continued bright he wished to point out that their present satisfactory state could only be counted upon so long as business remained good. The increased profit in 1895 was due to the extension of commercial enterprise. In view of the encouraging reports from Colonial agencies the Directors had decided to retain the advertisement branch of their business, for which no further outlay would be necessary A dividend of 2½ per cent., making 5 per cent. for the year, was declared.

**STOCK EXCHANGE NOTICES**.—The Stock Exchange Committee have ordered the undermentioned securities to be quoted in the official list : 22,500 Six per Cent. Cumulative Preference shares (Nos. 30,001 to 52,500) and 22,500 Ordinary shares (Nos. 1 to 22,500) of Willans and Robinson (Limited) ; and £300,000 Four per Cent. First Mortgage debentures (Nos. 1 to 3,000), in lieu of the £200,000 Four and a-Half debentures now quoted, of the India Rubber Company. Application has also been made to the Committee to appoint a special settling day and to grant a quotation to the Chelsea Electricity Supply Company (Limited) for the recent issue of 12,000 ordinary £5 shares.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED)**.—This Company's traffic receipts for the week ended May 22nd, after deducting 17 per cent of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,710.

**WILLANS AND ROBINSON (LIMITED)**.—From our advertisement columns it will be seen that this Company invite applications for £100,000 Four per Cent. First Mortgage Debenture Stock, payable—£10 on application, £10 on allotment, £40 on July 31 next, and £40 on January 31, 1897. The capital of the Company is £300,000, divided into 30,000 Six per Cent. Preference Shares and 30,000 Ordinary Shares of £5 each, of which 22,500 Preference and a similar number of Ordinary Shares have been issued and are fully paid. The present Debenture issue is secured by a charge upon the whole of the property and assets of the Company, and is required for completing the Company's extensive new works at Rugby, for providing additional plant and machinery and for further working capital. The prospectus states that the rate of increase in business is so rapid that the horse-power ordered during the first four months of the present year exceeds that of the whole of 1895 (27,883 I.H.P.), which showed a remarkable increase on the preceding year's figures. In addition to the Willans engine, the Company propose to manufacture the Niclausse water-tube boiler on a large scale at the new Rugby works. The profits of the Company for 1894 and 1895 (after allowing for interest on debentures and mortgages taken over from the old Company, all of which have since been paid off) were £15,708 and £23,275 respectively. Dividends have been paid at the rate of 7 per cent. per annum on the Ordinary shares, and, in addition, handsome reserve and depreciation accounts have been established. Application is to be made in due course for a Stock Exchange quotation. Prospectuses and forms of application can be obtained at the Company's temporary London offices, 14, George-street, Mansion House, E.C., as well as from the Company's bankers, solicitors, and brokers, and at the Thames Ditton works. The subscription list opens on Monday, and will be closed at 4 p.m. on Tuesday. Everything points to the continued prosperity of the Company, and there can be no doubt that a valuable home investment is here offered. We look forward to the subscriptions to this issue being much in excess of the amount of the issue.

# THE
# UNIVERSAL STEAM ENGINE
## (RAWORTH'S PATENT).

**In consequence of the large and increasing demand which has sprung up for this Engine since its introduction to the public (see *Engineering* of 28th Feb., 1896), the Directors of the BRUSH ELECTRICAL ENGINEERING COMPANY have authorised a large EXTENSION of their WORKS. Building operations have commenced and will be completed in August in time to cope with the Autumn trade.**

## UNDERGROUND MAINS.

## CALLENDER'S BITUMEN TELEGRAPH & WATERPROOF COMPANY, Ltd.

MANUFACTURERS OF

**ELECTRIC LIGHT CABLES, MAINS, CONDUITS AND ACCESSORIES.**

**Engineers and Contractors. Ironfounders and Coppersmiths. Makers of Lead Tube and Pipes. Bitumen Refiners**

**Head Office: 90, CANNON STREET, LONDON, E.C.**

Telephone No. 15133. Telegraph Address: "CALLENDER LONDON."

**Factory—ERITH MARSHES, KENT.**

**LIVERPOOL—Oldham Place, Renshaw Street. BIRMINGHAM—58, Water Street.**

**NOTTINGHAM—King John's Chambers, Bridlesmith Gate. GLASGOW—Great Western Road, Kelvinside.**

Also Contractors for underground Mains at ABERDEEN, COATBRIDGE, BURNLEY, LANCASTER, HUDDERSFIELD, SHEFFIELD, HULL, OXFORD HANLEY, CHELSEA, &c., &c.

The CALLENDER COMPANY is prepared to undertake the laying of Underground Mains, including all excavation and reinstatement of paving, building boxes, feeder points, or transformer chambers, erecting lamp posts, pillars and all other accessories required for the complete equipment of the distribution network of a Central Station, for either HIGH or LOW TENSION with CONTINUOUS or ALTERNATING CURRENTS —

1. With Vulcanised Bitumen Cables laid solid in Bitumen.
2. Or Drawn into CALLENDER-WEBBER or CALLENDER-RAWORTH Conduits, or into Pipes.
3. With Lead-Sheathed Cables either Single Conductor, Concentric, or Triple Concentric, armoured and laid direct in the earth.

**Price 1s., post free 1s. 3d. Annual Subscription, 12s. 6d. post free, abroad 14s.**

## "THE ENGINEERING MAGAZINE:"

An American Monthly Periodical, having an extensive sale and containing popularly-written critical articles on Electrical Engineering and Social Subjects by leading writers.

**CONTENTS OF THE MAY ISSUE (No. 2, Vol. XI.).**

THE PRESENT VALUE AND PURCHASING POWER OF GOLD—H. M. Chance.
QUACKERY IN ENGINEERING EDUCATION—Edgar Kidwell.
THE VAST IMPORTANCE OF THE COKE INDUSTRY—John Fulton.
DEVELOPMENT OF ELECTRIC LIGHTING ENGINES—H. Lindley.
ARE BRITISH RAILROAD STOCKS GOOD INVESTMENTS?—Thos. F. Woodlock.
ELECTRICITY AND THE HORSELESS CARRIAGE PROBLEM—W. Baxter, Jun.
POINTS IN THE SELECTION OF STEAM ENGINES—W. H. Wakeman.
MODERN MACHINE SHOP ECONOMICS. II.—Horace L. Arnold.
MINOR MINERAL PRODUCTS OF THE UNITED STATES. I.—David T. Day.
RESTRAINTS UPON THE PRACTICE OF ARCHITECTURE—J. B. Robinson.

Each issue of the Magazine also contains—

**A Complete Index of the Contents of the World's Technical Press.**

THE ENGINEERING MAGAZINE is profusely illustrated and forms a handsome six-monthly volume. A complete Index to the Contents of the Magazine from the Commencement will be forwarded post free on request.

**A Specimen Back Number will be forwarded on receipt of 6d. to defray postage, &c.**

**European Agent: GEO. TUCKER, Publisher, "THE ELECTRICIAN" PRINTING & PUBLISHING CO., Ltd.**
**SALISBURY COURT, FLEET STREET, LONDON, E.C.**

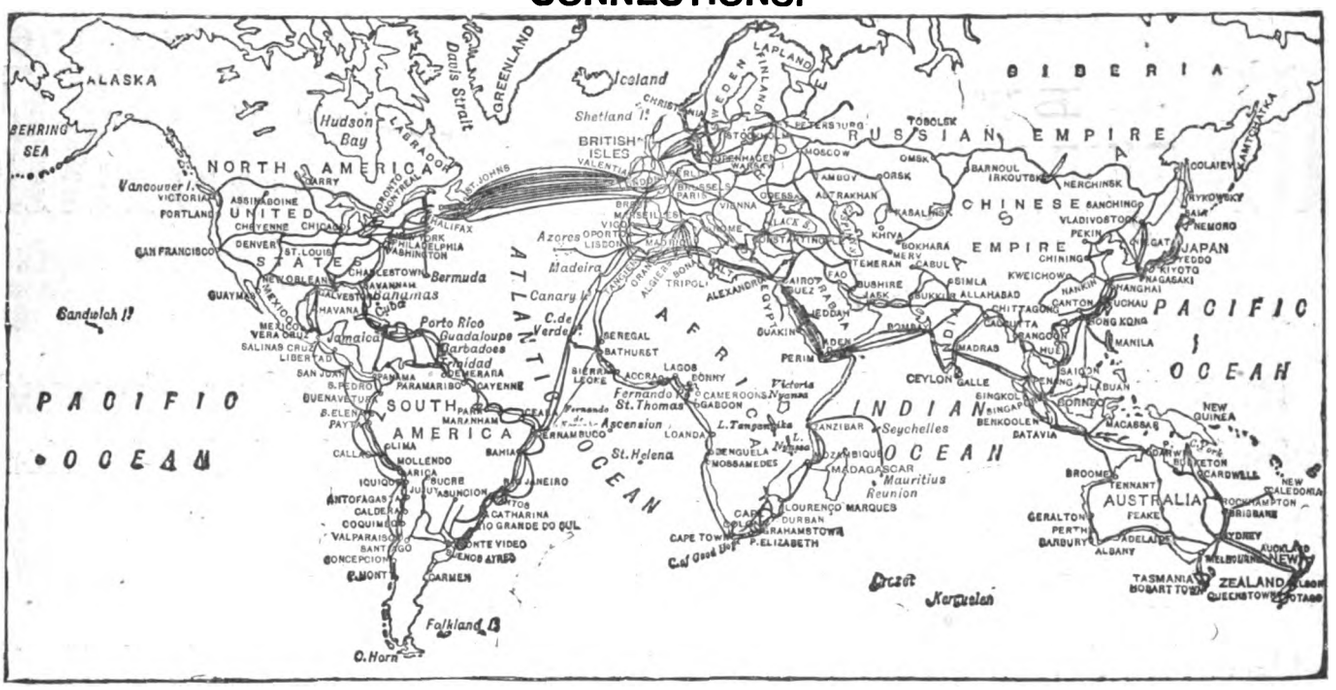
## THE EASTERN TELEGRAPH COMPANY'S SYSTEM AND ITS GENERAL CONNECTIONS.



THE

# EASTERN TELEGRAPH COMPANY, LIMITED.

IN CONNECTION WITH THE

**EASTERN EXTENSION (AUSTRALASIA AND CHINA), BRAZILIAN SUBMARINE, EASTERN AND SOUTH AFRICAN, EUROPE AND AZORES, WEST AFRICAN AND AFRICAN DIRECT TELEGRAPH COMPANIES.**

By DIRECT TRIPLICATE CABLES, to Spain, Portugal, Gibraltar, Malta, Egypt, Aden, and India.

By DIRECT DUPLICATE CABLE ROUTES to Madeira, St. Vincent, Brazil, Argentine Republic, Uruguay, also to Peru, Chili, and other parts of South America; and to Suakin, Perim, Penang, Malacca, Singapore, Labuan, Java, Australia, New Zealand, Tasmania, New Caledonia, Bangkok, Cambodia, Saigon, Tonquin, Hainan, China.

By ALTERNATIVE CABLES to Zanzibar, Mombasa, Mozambique (duplicate), Lourenço Marques (Delagoa Bay), Durban and Capetown; Bathurst, Sierra Leone, Accra, Lagos, Bonny, Bolama, Bissao, Cameroons, St. Thome, Principe, Loanda, Benguella, Mossamedes, Conakry, Grand Bassam, and Gaboon.

By SINGLE CABLE to the Azores, Tangier, Tripoli, Cyprus, Seychelles, Mauritius, and Manila.

Telegrams should be sent from the Company's Stations—

**LONDON—11, OLD BROAD STREET, E.C.; 8, LEADENHALL STREET; 3, GREAT TOWER STREET; 42, PARLIAMENT STREET, S.W.; 206a, WINCHESTER HOUSE, E.C.; 37, HOLBORN VIADUCT, E.C.; FOREIGN AUCTION HALL, COVENT GARDEN MARKET, W.C., and 449, STRAND, W.C.**

**MANCHESTER—20, Brown Street.** **LIVERPOOL—K13, Exchange Buildings.**

**GLASGOW—141, BUCHANAN STREET.**

COMPANY'S LEVANT SYSTEM:

**Odessa, Constantinople, Dardanelles, Tenedos, Salonica, Smyrna, Chio, Syra, Candia, Rettimo, Canea, Sitia, Rhodes, Trieste, Corfu, Zante, Patras, Corinth, Athens, Cephalonia, Santa Maura, Tinos, Andros, Zea, and all the Greek Islands.**

The Company's Cables are worked by Muirhead's DUPLEX principle upon all its Main Sections.

In sending Telegrams from Postal Stations care should be taken to mark them— "VIA EASTERN," these words being signalled gratuitously by the Postal Authorities.

Books of Forms and Tariffs forwarded post free on application at the Company's Chief Offices as above, or at

**37, RUE CAUMARTIN, PARIS; and HOTEL DES POSTES ET TELEGRAPHES, MARSEILLES.**

Winchester House, 50, Old Broad Street, E.C. By Order, GEORGE DRAPER, *Secretary.*

# THE INDO-EUROPEAN TELEGRAPH COMPANY, LIMITED.

## Shortest and Most Direct Route to India and the Far East,

## BY SPECIAL WIRES.

## DIRECT OVERLAND TELEGRAPHS

CONNECTED WITH

**INDIA, CEYLON, BURMAH, PENANG, SINGAPORE, AND OTHER PLACES IN THE STRAITS SETTLEMENTS, CHINA, MANILA, COCHIN CHINA, JAPAN, JAVA, AUSTRALIA, NEW ZEALAND, NEW CALEDONIA, PERSIA, SOUTHERN RUSSIA, CONSTANTINOPLE, AND OTHER PLACES IN TURKEY AND THE EAST GENERALLY.**

**The greatest possible SPEED and ACCURACY in the Transmission of Messages are secured by the VERY LIMITED NUMBER of TRANSMITTING STATIONS on the LINE, by the use of INK-WRITING RECORDING INSTRUMENTS, by the employment of a Special Staff of Skilled ENGLISH TELEGRAPHISTS throughout the Line, and by a System of Control which is exercised over every Message.**

*Messages are accepted at the Company's Offices—*

**LONDON: 18, Old Broad Street, E.C., 6 and 8, Lime Street Square, and 10 and 11, Mincing Lane, E.C.**

**LIVERPOOL: Walmer Building, 6, Water Street.**

**MANCHESTER: 60, Spring Gardens.**

Where receipts are given gratis for the charges made and whence messages are sent direct by Special Wire, and at any Postal Telegraph Office throughout the Kingdom.

ALL TELEGRAMS SHOULD BE MARKED "VIA INDO."

No Charge is made by any Telegraph Station for the transmission of the "Via."

Books of Forms and Tariff Books containing Rules and Regulations, Lists of Stations, &c., are forwarded post free on application to the Company's Head Offices, 18, Old Broad Street, London, E.C.

W. ANDREWS, *Managing Director.*

**THE INDESTRUCTIBLE PAINT COMPANY, Ltd., 27, Cannon St., E.C.**

# BROWNING'S PRESERVATIVE ENAMEL PAINT,

**IN ANY COLOUR OR TINT.**

**READY MIXED. USEABLE AT ANY TIME.** For **SHIPS, STEAMERS, YACHTS** (inside or outside), **LAMP-POSTS** (Gas and Electric) and for **ALL PURPOSES** where a hard and washable surface is essential. Has stood years of rough wear.

**THE INDESTRUCTIBLE PAINT** resists the action of acids and alkalies. Invaluable for Iron Structures, Roofing, Gas Tanks, &c LASTS WELL WHERE OTHER PAINTS ARE USELESS, NOT AFFECTED BY FUMES, GASES, SUDDEN CHANGES OF TEMPERATURE, &c.

**BROWNING'S PRESERVATIVE ANTI-FOULING COMPOSITIONS.**

**BROWNING'S COLOURLESS PRESERVATIVE SOLUTION** is a Perfect Cure for Damp Walls.

Makes Bricks, Porous Stone, Cement, &c., weatherproof. It was applied to **CLEOPATRA'S NEEDLE IN MAY, 1879,** and after eleven years exposure to the trying climate of London, Mr. Dixon, C.E. (who brought the Obelisk to London), described the successful result in *The Times*, May 28th, 1890.

**THE PAINTS and the SOLUTION SECURED the HIGHEST AWARDS at each of the EXHIBITIONS—**

**FISHERIES, HEALTH, and INVENTIONS, in 1883, 1884, and 1885.** *Telegraphic Address: "WEATHERPROOF LONDON."*

# HALLOWEEN.

FOR

INDIGESTION, WIND, BILE, SICKNESS, HEADACHE.

Also the VALUABLE ELECTRICAL PLANT, comprising Dynamos, Motors, Volt and Ammeters, Galvanometers, Wheatstone Bridges, Meters, Resistances, Switches, 15 miles of Vulcanised Cable, Telephones, Cast Iron Poles, Stays, Standards, Insulators, &c. Also the OFFICE FURNITURE, including two Safes, Typewriter, Desk, Tables, &c.

On view day preceding and morning of Sale. Admission by Catalogue only, which may be obtained from the Auctioneers, PERCY HUDDLESTON & CO., 72, Finsbury Pavement, LONDON, E.C.; 20, Chapel Works, LIVERPOOL; and 47, Grand Parade, BRIGHTON.

## TENDERS INVITED.

### BOROUGH OF SHOREDITCH.

ELECTRIC LIGHTING OF DUST DESTRUCTOR AND ELECTRICITY SUPPLY STATION, SHOREDITCH.

CONTRACT No. 6.

The SHOREDITCH VESTRY INVITE TENDERS FOR:—

The SUPPLY and FIXING of INSULATED CONDUITS, CABLES, SWITCH and FUSE BOARDS, and all SUNDRY FITTINGS and MATERIALS for INSTALLING the ELECTRIC LIGHT in their new Dust Destructor and Electricity Supply Station, Coronet-street, Shoreditch.

Specifications, with Forms of Tender, can be obtained, on and after June 5th, from the Consulting Engineers, Messrs. Kincaid, Waller and Manville, 29, Gt. George-street, Westminster, on payment of Three Guineas, which sum will be returned on receipt of a bona fide tender.

The Vestry do not bind themselves to accept the lowest or any tender; and Contractors whose tenders are accepted shall enter into a formal agreement under seal with sufficient sureties for the due fulfillment of their respective Contracts.

Trade Union rates of wages and hours to be observed.

Sealed Tenders, endorsed "Electric Lighting Tender for Wiring," to be sent at or before 4 p.m. on Tuesday, June 16th, 1896, to

H. MANSFIELD ROBINSON, Clerk and Solicitor.

Town Hall, Old-street, E.C.

### COUNTY BOROUGH OF BURNLEY.

TENDERS FOR ELECTRIC CABLES.

The CORPORATION of BURNLEY invite TENDERS for the SUPPLY and DELIVERY at their Electric Lighting Station, Burnley, of ARMOURED CONCENTRIC UNDERGROUND CABLES. Specification, Schedule of Quantities and Forms of Tender may be obtained on application to Mr. W. R. Wright, the Borough Electrical Engineer, on payment of a deposit of £1. 1s., which will be returned on receipt of a bona fide tender. Sealed tenders endorsed "Tender for Cables" and addressed to the "Chairman of the Electric Lighting Sub-Committee, Town Hall, Burnley," must be delivered on or before Wednesday, the 24th instant.

By Order,

WM. T. FULLALOVE, Town Clerk.

Town Hall, Burnley.
3rd June, 1896.

THE

**BRITISH ELECTRIC TRACTION (PIONEER) CO.,**

LIMITED.

## TENDERS INVITED.

### CALEDONIAN RAILWAY COMPANY.

CONTRACTS FOR STORES.

The DIRECTORS of the CALEDONIAN RAILWAY COMPANY are prepared to receive TENDERS for the SUPPLY of the undermentioned STORES, for Twelve months, from 1st August, 1896:—

| Class No. | |
|---|---|
| 1 | Barrows. |
| 2 | Bolts and Nuts. |
| 5 | Bricks, Clay, Lime, &c. |
| 6 | Brooms, Birch and Heather. |
| 7 | Brushes. |
| 9 | Candles and Soap. |
| 10 | Canvas. |
| 11 | Carriage Furnishings. |
| 12 | Carriage Laces |
| 13 | Carriage Trimmings. |
| 17 | Colours. |
| 18 | Copper Rivets, &c. |
| 19 | Cotton Waste and Sponge Cloths. |
| 20 | Crucibles. |
| 21 | Drysalteries. |
| 24 | Gas and Water Fittings. |
| 25 | Glass. |
| 27 | Hammer Shafts. |
| 28 | Hardware. |
| 29 | India-Rubber. |
| 32 | Iron Chain. |
| 33 | Iron Rivets. |
| 34 | Galvanised Wire and Wire Fencing Requisites. |
| 37 | Lamps and Lamp Furnishings. |
| 38 | Lamp-Wick Cottons. |
| 39 | Leather. |
| 40 | Locks. |
| 41 | Nails, Sprigs and Tacks. |
| 42 | Oils and Grease. |
| 47 | Rail Chair Spikes and Fish Bolts. |
| 48 | Ropes, Cordage and Twines. |
| 49 | Screws. |
| 50 | Shovels, Spades and Graips. |
| 52 | Spelter, Tin and Lead. |
| 59 | Sundries. |
| 60 | Telegraph and Electric Appliances. |
| 64 | Timepieces. |
| 65 | Tinwork. |
| 66 | Tools. |

Specifications and Forms of Tender, and any other necessary information, may be obtained, on and after the 1st June, from Mr. Jas. Lorimer, Superintendent of Stores, Caledonian Railway, Charles-street, St. Rollox, Glasgow.

Patterns may be inspected on and after Monday, 1st June, from 9 a.m. till 5 p.m., at the Company's Stores, Charles-street, St. Rollox. (Saturday, 9 a.m. till 1 p.m.)

Tenders, endorsed "Tender for Stores," to be lodged with the Secretary, 302, Buchanan-street, Glasgow, not later than MONDAY, 15th June, 1896.

The Directors do not bind themselves to accept the lowest or any offer.

J. BLACKBURN, Secretary.

Company's Offices, 302, Buchanan-street, Glasgow.
29th May, 1896.

### CITY OF LEEDS.

TO ELECTRICAL ENGINEERS, CONTRACTORS AND OTHERS:—

The COUNCIL require TENDERS for an ELECTRICAL INSTALLATION sufficient for the working by the overhead system of haulage, a double track of Tramway seven miles long. The work will be divided into the following Contracts:—

1. POLES for supporting Trolley Wire.
2. UNDERGROUND CONDUITS and CONDUCTORS.
3. TROLLEY WIRE and attachments.
4. MOTOR CARS.
5. ACCUMULATORS and SWITCHES.
6. STEAM ENGINES.
7. DYNAMOS, SWITCHBOARDS and ACCESSORIES.

Tenders endorsed with the number of the contract must be sent in, addressed to the Town Clerk, Town Hall, Leeds, not later than JUNE 20th next.

Particulars, plans and forms of Tender may be had (on payment of a deposit of £2 2s. for each contract, which will be returned on receipt of a bona fide Tender) from the City Engineer, Municipal Buildings, Leeds, or from

DR. JOHN HOPKINSON, F.R.S.,
5, Victoria-street, Westminster, S.W.

A COLONIAL FIRM with OFFICES and WAREHOUSES in NEW ZEALAND and AGENCIES thoughout AUSTRALASIA, is open to REPRESENT a few good ENGLISH and CONTINENTAL HOUSES in ELECTRICAL MACHINERY and SUPPLIES (Mining Machinery preferred).

TRAVELLERS CONSTANTLY AT WORK.

## SITUATIONS VACANT AND WANTED.

A LARGE Continental Manufacturing Joint Stock Company in the electrical line, intending to open a London branch, seeks the services of a MANAGER; liberal terms. Must be thoroughly acquainted with the trade, and have good introductions. Guarantee required.—Address "P. C.," Buecker's Hotel, Finsbury-square, London, E.C.

MANUFACTURER of good Incandescent Lamp requires AGENTS in all important towns in the United Kingdom.—Apply by letter to "LAMPS," care of *Electrical Review*, 22, Paternoster-row, London.

COIL-WINDING, LACQUERING and POLISHING GIRLS WANTED, used to lacquering and polishing small electrical instruments.—State wages required and experience to "TELEPHONE," *Electrician* Office Salisbury-court, Fleet-street, E.C.

ELECTRICAL ENGINEER seeks ENGAGEMENT, capable of estimating for and carrying out electrical wiring. Good general experience, moderate salary.—Address, "G. S.", *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ENGINEER, nine years' experience in factory, installation and station work, well up in designing and estimating, highest references, seeks ENGAGEMENT.—2217, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

WANTED, situation as INVENTOR'S MODEL MAKER, used to small mechanical work.—Address, W. WATSON, Green Dragon Hotel, Beverley.

ELECTRICAL ENGINEER seeks ENGAGEMENT. Capable of estimating and carrying out installations. Good experience.—Address "G. S.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

## WANTED, and FOR SALE.

PLATINUM UTENSILS, SCRAP, LAMP TOPS.—Best prices given by Derby and Co., 44, Clerkenwell-road, London, E.C. N.B.—Platinum sold

WANTED good SECONDHAND 100 HORSE-POWER STEAM ENGINE and 75-UNIT ALTERNATOR.—Price and particulars to "X. X.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

TO CYCLE, MOTOR CAR, ELECTRIC COMPANIES AND OTHERS.

FOR SALE, CASTLE IRON AND STEEL WORKS, Hadley, Wellington, Salop. Rolling mills for iron, rods, hoops, wire; large shops and buildings; £10,000 worth plant, cost £100,000; L. and N. W. sidings into works; canal basin; cheap coal; splendid works and site for above companies.—B. P. BLOCKLEY, Bloxwich, Staffs.

ACCUMULATOR CHARGING.—C. H. CATHCART and CO., having plant specially adapted for this purpose, Charge Cells of all sizes promptly, thoroughly and cheaply. Terms on application. Accumulators on Hire for temporary lighting, experimental uses, &c.—3, Dorset-buildings, Salisbury-square, Fleet-street, E.C. (Telephone No. 65,266.)

ELECTRICIANS.—NOTICE to EMPLOYERS.—Please note we have a number of First-Class ELECTRICAL MEN upon our Books. Kindly send us particulars of any VACANCIES you may have. We can introduce you, free of charge, to the best men now at liberty.
Address, CHAS. RICHARDSON and CO., Engineers' Bureau, 342, Strand, London, W.C

PARTNERSHIPS.—ELECTRICAL ENGINEERS and others WANTING PARTNERS, or wishing to SELL, can be introduced to Clients with Capital; and GENTLEMEN Seeking Investments can obtain personally (or through their solicitors) particulars of bona-fide OPENINGS. Strictest confidence observed.—Address, CHAS. RICHARDSON and CO., 342, Strand, London, W.C.

HANDY GUIDE TO PATENT LAW AND PRACTICE.

By C. F. EMERY, LL.M., of the Inner Temple, Barrister-at-Law.

"The learned author of this volume has compressed within the limits of some 300 pages all the law and procedure relating to patents, commendable alike from the point of view of typography and arrangement."—*Electrician.*

"Mr. G. F. Emery, of the Inner Temple, is already favourably known as the author of concise legal textbooks. . . . The book is well conceived and carefully executed."—*Manchester Guardian.*

"It is clearly and concisely written and seems to contain all information that is of practical value as to obtaining a patent."—*Law Times.*

EFFINGHAM WILSON, Royal Exchange, E.C.

A HANDSOME AND INTERESTING GIFT BOOK.

THE ARTEMIS LIBRARY. Crown 8vo, illustrated, gilt edges, 7s. 6d.

THE PEOPLE OF THE MOON.

A Novel. By TREMLETT CARTER.

Illustrated by D'AGUILCOURT.

"This remarkable book bears upon every page evidence of scientific knowledge and vivid imagination. . . . We congratulate the author."—*Nature.*

"The reader will travel through a strange country indeed, and among an almost bewildering variety of marvels. The people of the moon seem to have carried scientific research and invention to a pitch at which we poor earth mortals can hardly hope to arrive in the course of another thousand years or so."—*The Electrician.*

"Tremlett Carter has a fantastic imagination, and takes his readers through many strange experiences."—*Black and White.*

"There is a power of fantastic description in the book that suits the curious scenery of d'Aguilcourt's illustrations."—*Daily Telegraph.*

"There is so much of the marvellous in Mr. Tremlett Carter's book, that at length we cease to be astonished at anything he chooses to tell us. A skilful use of scientific facts gives to the narrative a partial sense of verisimilitude. The book is boldly conceived and well written. The illustrations are of considerable merit."—*St. James's Gazette.*

"For daring originality and stupendous flights of imagination the work would be hard to beat. . . . The book is certainly pleasant reading, and capitally written from a literary point of view."—*Liverpool Mercury.*

"Electricity plays a very important part in the story, and the various uses to which it is put are both interesting and instructive, and doubtless are but forecasts of what will be some day. The book is well got up, and worth reading as fiction combined with possibility."—*Western Morning News.*

"There is imagination in this story, as well as skill in the telling."—*Daily News.*

"The tale is thrilling in the extreme and cleverly worked out."—*Graphic.*

"It is a book of marvels."—*Yorkshire Post.*

# SUBMARINE CABLE LAYING AND REPAIRING.

By H. D. WILKINSON, M.I.E.E.

The Author has given a detailed technical summary of modern practice in Manufacturing, Laying, Testing and Repairing a Submarine Telegraph Cable. The testing section and details of boardship practice have been prepared with the object and hope of helping men in the cable services who are looking further into these branches. In the work of cable laying and repairing the most exact scientific processes are called into ordinary use, and the service affords great scope for the exercise of engineering and electrical skill. The enterprise has a great deal before it as regards possibilities in research, improvements in instruments, processes and methods of working, and further extension of the cable systems. The description of the equipment of cable ships and the mechanical and electrical work carried on during the laying and repairing of a submarine cable will prove also to some not directly engaged in the profession, but nevertheless interested in the enterprise, a means of informing themselves as to the work which has to be done from the moment a new cable is projected until it is successfully laid and worked.

In this original work is described the procedure on board ship when removing a fault or break in a submerged cable, and the mechanical gear used in different vessels for this purpose. Further, as regards the electrical tests in use for the detection and localisation of faults, to consider the best and most recent practice, and the various difficulties that occur to the beginner. With a total length of nearly 140,000 miles of cable submerged, and a fleet of 36 steamers employed solely in laying and repairing cables, some idea may be gained of the vastness and importance of this enterprise, and the various interests it involves. Of late years many improvements have been introduced in the tests used for locating the positions of faults in cables, and these have resulted in a considerable saving to the owners in cost of maintenance.

The book will be found of quite exceptional interest, and the illustrations assist the text in an unusual degree.

TABLE OF CONTENTS:

**CHAPTER I.—The Cable Ship on Repairs.**

Speaking Apparatus—The Mark Buoy—Grapnels and Grappling—Special Grapnels—Cable Inboard—Buoying the Cable—Picking up—Types of Cable—Underrunning—Capacity of Tanks—Picking-up Gear—Removal of Fault—Joint in Core—Cable Splice—Slipping Splice—Cable Stoppers—Paying Out—Buoyed End Inboard—Final Splice and Completion of Repair—Regulations affecting Cable Ships at Sea—Buoying a Bight.

**CHAPTER II.—Types of Cable Ships.**

The Cable Ship "Faraday"—The Cable Ship "Store Nordiske" and "H. C. Oersted"—The Cable Ship "Monarch"—The Maintenance of Home and Continental Cables—The Cable Ship "Electra"—The Cable Ship "Mackay-Bennett"—The Cable Ship "Retriever"—Cable Depôts—Cable Gear on the "John Pender."

**CHAPTER III.—The Localisation of Faults.**

Preliminary—The Earth Overlap Test—Earth Overlap as a Loop—Cable Currents—Balancing to False Zero—Polarisation of Fault or Break—Improved Blavier—Mance Partial Earth Test—Mance Test for Fracture—Kennelly's Break Test—Battery E.M.F. by Varley Slides—Battery Resistance—Simultaneous Battery Resistance and E.M.F Tests—Loop Tests—Tests of Cable in Tank—Shipboard Galvanometers—Capacity Tests—Calibrating the Slides—Clark's Fall of Potential Test—The Polar Test.

**CHAPTER IV.—The Laying of Submarine Cables.**

Design and Manufacture—Shipment—Landing Shore-End—Surveying the Route—Cable House and Landline—Laying Main Cable—Final Tests.

**APPENDICES.**

Appendix to Kennelly's Break Test—Appendix re New Japanese Cable Steamer.

15 Plate 560 Amp.-hour Cell in Glass Box

# PRITCHETT ACCUMULATORS

**PLANTÉ TYPE.**

**From the ELECTRICAL STANDARDIZING INSTITUTION, LONDON.**

"The Cells we use for standardising purposes were supplied to us by yourselves in September, 1892, and have been in constant use ever since.

"The normal maximum output was stated to be 250 amperes per cell, that is, nearly 18 amperes per positive plate nine inches square, but we sometimes discharge them for short periods at three times this rate, so that each positive plate gives 54 amperes; indeed, they are occasionally deliberately short-circuited. Up to the present time no repairs have been needed, and they continue to do their work satisfactorily.

"You agreed to supply us with Cells which could be practically short-circuited without undue deterioration, and this we consider you have done."

**TWO RECENT TESTIMONIALS.**

***Price Lists and Trade Terms on Application.***

**From Messrs. F. H. ROYCE & CO., Ltd., MANCHESTER.**

"We have very great pleasure in testifying to the excellence of your Accumulators. We have, during the last few years, purchased a very considerable number of you as you know, and have always considered them, as we do now, the best in the market owing to the very great mechanical strength and large surface of the plates.

"If it would be of service to you at any time, we have no doubt we could get many of our customers using these Accumulators to give equally strong testimony as to their excellent features."

# THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

## ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 942. [Vol. No. 6. XXXVII.] FRIDAY, JUNE 5, 1896. PRICE SIXPENCE.

## NOTES.

A VERY lucid little article, by Dr. OLIVER LODGE, to be found elsewhere in the present issue, describes a few of his more recent experiments on Röntgen rays. Dr. LODGE finds that a *positive* charge has a peculiar reinforcing action upon the ray-emitting powers of a surface exposed to the cathodic radiation, but wisely refrains from hazarding an explanation of the phenomenon. Of greater interest are the experiments made in connection with the influence of magnetic lines of force. M. LAFAY (see *The Electrician*, Vol. XXXVI., April 3rd, p. 750) asserted that X-rays after passage through an electrified plate become amenable to the magnetic influence. As Dr. LODGE very truly remarked, this result would, if true, be profoundly important, since it would tend to the belief that X-ray phenomena were due to something in the nature of flying particles. Not a trace of the deflection or of the twist observable with *cathode* rays was found in the case of X-rays.

AN interesting letter which we publish this week, from the pen of M. BLONDEL, supplies us with a further *quotum* of historical notes relative to the action of the electric arc in distorting the wave form of the alternating current supplying it with power. M. BLONDEL shifts the date of the earliest indication of this effect back to 1881, and attributes to JOUBERT the distinction of having been the first to observe it. As will also be seen, M. BLONDEL's own subsequent contributions to the literature of this interesting line of research were many of them made at an early date, the question of the distortion of waves by the alternate-current arc having been analysed by him in a Paper which appeared in *La Lumière Electrique* of September 16, 1893. Basing his argument upon the researches which are described in that Paper, our correspondent now alleges that both Mr. FRITH's and Mr. STEINMETZ's opposing conclusions are erroneous, owing to the fact that these investigators do not appear to have taken account of the influence exerted by the nature of the carbons. Thus the plot thickens, and things resolve themselves into an interesting triangular duel.

LET us briefly review the positions of the three contending parties. In the first instance, Mr. FRITH brought before the Physical Society some curves which he had already, in 1891, communicated to the Manchester Literary and Philosophical Society. These curves represented the influence of an alternating arc upon the wave form developed by a "Wilde" iron-cored alternator, and Mr. FRITH ventured to state that the curves showed "the great effect that the arc has on the wave form, and also how this effect can be destroyed by placing resistance in series with the arc." The general conclusion drawn by Mr. FRITH was that when the arc is permitted to have a preponderating influence it will alter the wave to the form required for the maximum efficiency, that is to say, the flat-topped wave. Now we come to Mr. STEINMETZ. In our issue of May 22nd, we published a letter in which he described some experiments performed by Messrs. TOBEY and WALBRIDGE, in 1890, these investigators running arcs in series on a Stanley alternator. The wave form, which ordinarily was sinusoidal, became distorted into "the most exaggerated form of a flat-topped wave—that is, a sharp double peak with a deep hollow between." Mr. STEINMETZ states that this effect was satisfactorily explained by Prof. PUPIN, who attributed it to "the periodically varying resistance of the arc, which is extremely high at or near zero value of current, low near the maximum value." The Stanley machine used possessed very high internal reaction, and Mr. STEINMETZ asserts that, had a machine possessing very low internal reaction been used, the wave of current would have been "distorted to single peakedness, that is, to the shape undesirable for arc lighting." How Mr. STEINMETZ knows this he does not say; but the assertion is one of vital importance to the question at issue. Here we have, then, M. BLONDEL stating that the nature of the influence of the arc depends upon the quality of the carbons, and Mr. STEINMETZ stating that it depends upon the internal reaction of the alternator. What is the general law? Are both these conclusions right, or are they both in some way incorrect? In fact, what are the general conditions under which an alternating arc can distort the wave into the most efficient form, as we know from Mr. FRITH's researches it sometimes does?

THE Fourth Report of the Royal Commission on Electrical Communication with Lighthouses and Light-Vessels, which will be found in another column, contains some exceedingly interesting particulars with regard to the experience obtained in connection with various solutions of this peculiarly difficult problem. As will be seen by the Report, the experience is not altogether satisfactory, and it is proposed to try the induction system, supplemented by Mr. SYDNEY EVERSHED's

Digitized by Google

ingenious call-relay. Not the least valuable feature of the Report is the information relating to and the success attained with the Fastnet discontinuous system of communication. This system has proved an unqualified success, and may confidently be recommended for all rock lighthouses in exposed positions. Notwithstanding the great attention which was at one time called to the Danish system, it is evident that the members of the Royal Commission do not think very highly of it, nor does it appear to offer many suggestions of first-class importance applicable to this country.

THE principle of Mr. EVERSHED's call-relay is as follows: A rectangle of copper wire, one end of which is clamped to an insulating support, is placed between the poles of a powerful permanent magnet. This rectangle is timed to vibrate when traversed by the special calling current, the frequency (20 to 40 ∿) of which is regulated by a tuning fork. In its excursions it comes in contact with a second rectangle timed in unison with it, and, closing a local circuit, rings a call bell. Two similar rectangles are used to prevent accidental contacts due to mechanical jars. The Royal Commission propose to give this pretty device an early trial on the East Goodwin lightship. The vessel is, of course, surrounded at the bottom of the sea by a huge ring main, which forms the primary coil of the induction system, the secondary coil being wound round the outside of the vessel, the iron frame of which forms a suitable core. A rapidly driven contact-breaker sends an intermittent current through the primary line, giving rise to a buzzing in the telephone connected to the secondary circuit, the regular interruption of which when signalling is effected by a Morse key.

IT has been said that "history might possibly miss most of its striking episodes if every actor could know the work to which he was putting his hand." We doubt it. Individuals to whose lot it falls to make history are not in the nature of things likely to be deterred from so doing by the possible miscarriage of their schemes. And still less does the remark apply to inventors. The world, we feel sure, has not missed any striking invention by reason of the inventor's fears as to its possible abuse or misuse. At the same time it is not without interest and instruction to compare the glowing anticipations with which great discoveries are so frequently hailed with the business-like estimate of profit—and loss, of a subsequent generation. MORSE's famous first message, "What hath GOD wrought," and the messages exchanged between the Queen and the President of the United States, celebrating the successful laying of the Atlantic cable of 1858, sanguine and sonorous as they were, were no exaggerated expression of contemporary feeling; yet before the century which has witnessed these truly tremendous events has fully run its course, the very sober, not to say sombre, estimate contained in Mr. LECKY's ponderous work on "Democracy and Liberty" does not strike the average reader as unduly pessimistic. Below we quote in full the verdict of Mr. WILLIAM EDWARD HARTPOLE LECKY on the telegraph, considered as a factor in social and political evolution. It will be seen that almost the sole unqualified gain which he is willing to admit is the development of an influential provincial Press—an important item to the credit of telegraphy, no doubt, but not precisely the result contemplated by President BUCHANAN when he ecstatically telegraphed on August 16, 1858: "May the Atlantic Telegraph, under the blessing of Heaven, prove to be a bond of perpetual peace and friendship between the kindred nations, and an instrument destined by Divine Providence to diffuse religion, civilisation, liberty and law throughout the world. . . ."

The growth of an independent provincial spirit has been much accelerated by the telegraph. The political influence of this great invention, though various and chequered, has been scarcely less powerful than that of the railway. It has brought the distant dependencies of the Empire into far closer connection with the mother country; but it is very doubtful whether the power it has given to the Home Ministers of continually meddling with the details of their administration is a good thing, and there have been times of disagreement when a rapid communication between foreign countries might have led rather to war than to peace. Government by telegraph is a serious, dangerous thing; and it has been often said that if an Atlantic telegraph had connected England with the United States in the first excitement of the "Trent" affair, enabling the two nations, when their blood was still hot, to exchange their impressions, a war could scarcely have been averted. The telegraph, on the other hand, has greatly strengthened the central Government in repressing insurrections, protecting property, and punishing crime. It has, at least, modified the Irish difficulty by bringing Dublin within a few minutes' communication of London. It has had enormous economical consequences: equalising prices, stimulating speculation, destroying, in a great measure, the advantage of priority of time which the inhabitants of great centres naturally had in many competitions. The effect, however, on which I would now specially dwell is its great power in decentralising politics. The provincial Press, no doubt, owes much to the repeal of the stamp duty and the paper duty; but the immense development and importance it has assumed within the lifetime of men who are still of middle age are mainly due to the existence of telegraphic communication.

A SOBER summing-up in all truth, but, even so, more flattering than Lord DUFFERIN's recent pronouncement at the annual banquet of the British Chamber of Commerce of Paris. "Thanks to the telegraph," said this authority, "the globe itself has become a mere bundle of nerves, and the slightest disturbance at any one point of the system sends a portentous tremor through its morbidly-sensitive surface."

IF we are to judge by the programme of the First Annual Convention of the Municipal Electrical Association, the municipal electrical engineer hath an inordinate appetite. On the first day four Papers and a Presidential Address are to be read, or taken as read, and discussed, between 10:15 and luncheon time, and the remainder of the bill of fare apparently presupposes a digestive apparatus scarcely less Gargantuan. The quantity of matter to be dealt with is not less abnormal than its variety and interest; if the contents of the Papers bear out their titles, the municipal electrical engineers will have exhausted all possible topics of discussion at their very first meeting. The word "convention" has, it is true, many meanings and shades of meaning; it may denote "a meeting or an assembly of persons, especially of delegates or representatives, to accomplish some specific object, civil, social, political, or ecclesiastical"; or it may be "an extraordinary assembly of the Parliament or estates of the realm, held without the King's writ." But the term does not strike us as exactly appropriate to a modest gathering of hard-working English engineers. There is a certain grandilo-

Digitized by Google

quent sound about the word "convention" when so applied, which seems to come to us from across the broad Atlantic. It is to be hoped that the use of this little word is not symptomatic of any other transatlantic importations.

**Society of Arts.**—The annual *conversazione* of this Society will be held at the South Kensington Museum, on Wednesday, June 17th.

**Röntgen Rays.**—On Wednesday next, June 10th, Prof. J. J. Thomson will deliver the Reade Lecture at Cambridge. The subject will be "Röntgen Rays."

**Cable Interruptions and Repair :—**

| | Date of Interruption. | Date of Repair. |
|---|---|---|
| Brest– St. Pierre ..... ..... | June, 1895 ... | May 21, 1896 |
| Puerto Plata—Martinique..... | Dec. 19, 1895 ... | — |
| Ceara—Maranham ..... | April 28, 1896 ... | — |
| Monte Alegre—Santarem..... | May 5, 1896 ... | — |

**A Parisian "Metropolitan" Railway System.**—A notice emanating from the Prefecture of the Seine, and published in the *Bulletin Municipal Officiel* of May 19th, announces that the plans of a proposed autonomous narrow-gauge *electric* railway will be on view in each of the 20 mairies of Paris from May 18th to June 18th, where objections may be lodged.

**Proposed Electric Light and Power Supply at Leeds.**—An offer has been made to the Leeds Corporation by the Yorkshire House-to-House Company to supply the energy required for running the proposed electric trams between Roundhay and Kirkstall.

**Electric Mountain Railway at Zermatt.**—With reference to our note in last week's issue on the electric rack railway which is to connect Zermatt with the Gornergrat, we can now add that the system to be employed will be the polyphase overhead trolley system, similar to that employed at Lugano. The contract for the whole electrical equipment has been given to Messrs. Brown, Boveri and Co., of Baden, Switzerland.

**American Institute of Electrical Engineers.**—The annual meeting for election of officers of the American Institute of Electrical Engineers was held on May 19th, when the following were elected :—President, Louis Duncan ; Vice-Presidents, Charles P. Steinmetz, Harris J. Ryan, Wilbur M. Stine ; Managers, John W. Lieb, jun., F. A. Pickernell, William L. Puffer, L. B. Stillwell ; Secretary, Ralph W. Pope ; Treasurer, George A. Hamilton.

**The Guernsey Authorities and the Telephone Wires.**—The High-street at Guernsey was temporarily closed on Wednesday whilst workmen removed all telephone wires, which, it is alleged, the National Telephone Company put up without the permission of the authorities, who object to lines crossing streets. The Company having failed to acknowledge the notice to remove the lines the authorities took the matter into their own hands.

**An Historical Patent.**—But that the patent had already lapsed, Tuesday next, June 9th, would witness the expiry of the historically interesting patent No. 2,712, of 1882, granted to Franz Krizik and Ludwig Piette, of Pilsen, for "Improvements in Electric Lamps." The invention relates to the use of a tapered iron core for the solenoids of arc lamps, and the form of lamp in which this invention was embodied has been known commonly as the Pilsen lamp.

**Jungfrau Railway.**—In connection with the international competition for the best solution of a number of questions connected with the construction and working of an electric railway up the Jungfrau, details of which we published in *The Electrician* of March 13th last, 130 schemes have so far been received as follows :—From Switzerland there came 43 schemes, from Germany 42, Italy 10, England and America 9, France 6, Austria 5, Holland 2, and Belgium, Servia, Russia and Algeria 1 each.

**Royal Society.**—Yesterday the annual election of Fellows took place, and was followed by the reading of Papers, among others one by Prof. Dewar and Dr. Fleming : (1) "On the Electrical Resistivity of Bismuth at the Temperature of Liquid Air," (2) "On the Electrical Resistivity of Pure Mercury at the Temperature of Liquid Air" ; another by Prof. F. G. Baily, "The Hysteresis of Iron and Iron and Steel in a Rotating Magnetic Field" ; and another by Mr. C. Chree, "Observations on Atmospheric Electricity at the Kew Observatory."

**Institution of Electrical Engineers.**—At the special general meeting held on Friday last the proposed alterations in the Articles of Association, which we reprinted in our last issue, were, with the exception of a few minor amendments and additions, approved of. The proposals now await confirmation at a special general meeting to be held shortly.——The annual conversazione of the Institution will be held in the galleries of the Royal Institute of Painters in Water Colours on Thursday evening, June 25th.

**University College of South Wales and Monmouthshire.**—On Monday last the new engineering laboratory of this college was opened by Mr. F. W. Harries, master of the Drapers' Company. For the purpose of this laboratory the Government granted £20,000, local subscribers got together another £20,000, and the Drapers' Company gave £10,000. Prof. Viriamu Jones, Principal of the College, in proposing a vote of thanks to the Drapers' Company, said that the conditions upon which the grant was made would most certainly be fulfilled.

**American Criticism of European Practice.**—The tendency of American practice, says the *Street Railway Review*, "is towards standardisation and simplification and cheapening of manufacture and maintenance, and to this is partly due, no doubt, the rapid growth of the electrical business in this country. The European engineer, on the other hand, must have everything technically correct and suited to each particular case, thereby giving rise to a great diversity of practice and complication of apparatus. An example of the latter was furnished the other day, when an examination of a trolley base sent from Germany, and considered the proper thing over there, revealed the fact that it had something over 100 parts."

**The Pacific Cable Conference.**—Lord Selborne (Under-Secretary for the Colonies) and Mr. G. H. Murray (of the Treasury) have been appointed British delegates to the Colonial Office Conference which is about to be held to consider the Pacific Cable scheme. Lord Selborne will act as chairman. The Conference, when it meets to-day, will therefore be constituted as follows : Lord Selborne and Mr. G. H. Murray (England), Sir Saul Samuel (New South Wales), Mr. Duncan Gillies (Victoria), Sir Donald Smith and Sir Mackenzie Bowell (Canada), and Mr. Fleming, Canadian expert on telegraphy, with Mr. W. H. Mercer, secretary. Mr. Chamberlain, it is understood, will occasionally attend the meetings.

**Institution of Civil Engineers.**—At the annual general meeting on Tuesday the Council for the Session 1896-97 was duly elected, when several members were placed on the governing body as representative of the profession outside the United Kingdom. The full list of the new Council is :—*President*, John Wolfe Barry, C.B., F.R.S. ; *Vice-Presidents*, W. H. Preece, C.B., F.R.S., Sir Douglas Fox, James Mansergh and William Anderson, C.B., D.C.L., F.R.S. ; *Other Members*, A. R. Binnie, Henry Deane, W. R. Galbraith, George Graham, J. H. Greathead, J. C. Hawkshaw, Charles Hawksley, John Hopkinson, jun., D Sc., F.R.S., A. B. W. Kennedy, LL.D., F.R.S., John Kennedy, G. Fosbery Lyster, Sir Guildford L. Molesworth, K.C.I.E., Sir Andrew Noble, K.C.B., F.R S., William Shelford, B. B. Stoney, LL.D., F.R.S., F. W. Webb, Sir. W. H. White, K.C.B., F.R.S., and Sir E. Leader Williams. Of these gentlemen Mr. Henry Deane represents Australia and Mr. John Kennedy Canada.

**Magnesium.**—In an article published in *Machinery*, an American technical journal, Prof. Thurston gives an account of some of the physical properties of magnesium. In the first place, its specific weight is as only about two-thirds that of aluminium, viz., 109lb. per cubic foot. It melts at 811°F., and has electrical conductivity equal to 41·2 per cent. that of pure copper. Its tenacity ranges from 22,000lb. up to 32,000lb. per square inch. Its elastic limit in the shape of wire is about 8,770lb. per square inch, and its elastic modulus about 1,945,000lb., or less than that of most stones. The cast metal has a much lower tenacity, ranging from 9,640lb. to 13,600lb. per square inch. Alloyed with aluminium up to 10

Digitized by Google

per cent. of magnesium, it increased the strength and elastic modulus of the former metal, but greater additions yield a weak and brittle alloy. Prof. Thurston further states that all attempts made at the Sibley College to form an alloy of copper and magnesium have completely failed, though much time and trouble were spent on the matter.

**American Pacific Cable.**—Those who favour the construction of a Pacific cable under the control of the American Government, says the *Western Electrician* of Chicago, "may well feel encouraged by the advancement of the movement lately. It was feared that the controversy over the Spaulding and Scrymser Bills under consideration in the Senate would result in the defeat of the project, as the friends of each measure refused to give way to those of the other. On May 6, however, a compromise was effected in the Committee on Foreign Relations which had both measures under consideration. The measure which Senator Frye was directed to report is in the shape of a Bill directing the Postmaster-General to contract with the lowest bidder for the construction of a telegraphic cable between the United States and Japan by the way of Hawaii and the Medway Islands. It is stipulated that the price shall not be in excess of $160,000 a year for a period of 20 years, during which time and for ever afterward the Company shall carry Government messages free of all cost. It is hoped that this will prove a practical solution of this perplexing question."

**The Tramway System of Chicago.**—From statistics just issued it appears that ten years ago there were but four tramway companies in Chicago, capitalised at 2¼ million sterling, and working a street mileage of 90 miles (average capital cost therefore about £25,000 per mile). To-day there are 29 distinct concerns, having an aggregate capitalisation of 37½ millions sterling, and operating 342 miles of street mileage (nearly £110,000 per mile). Of the four systems in existence ten years ago three were worked entirely by horses, the fourth using both cable and horses. Now the horse car has practically disappeared from Chicago, the motive power at present being:—Surface roads—electric, 255 miles; cable, 42 miles; horse, 18 miles. Elevated roads—electric, 15 miles; steam, 11 miles. In addition to the roads now completed, construction work is rapidly progressing upon five surface and elevated roads, all to be worked by electricity and which will, when completed, increase the total city mileage to 400 miles. London has less than three miles of mechanically worked tramways, while the total street length of tramways is only 136 miles, all worked by horse power.

**An Exhibition of Galvanometers.**—The sixty-eighth general meeting of the Society of German Physicists and Physicians will be held at Frankfort-on-the-Main from September 21st to September 26th. There will be no general exhibition in connection with the meeting as hitherto, but several separate exhibitions by different branches are proposed. The sections of physics, meteorology and instrument making are arranging for an exhibition of galvanometers and another one of Röntgen ray apparatus, and they invite the co-operation of all who are interested in the different subjects. The programme for the galvanometer section is as follows: 1. Historical galvanometers up to the fifties; original instruments or good copies of the same by Schweigger, Poggendorff, Fechner, Nobili, Weber-Gauss, &c., are specially wanted, the instruments to be accompanied, if possible, by complete historical data. 2. Galvanometers of later date, up to the eighties, of Meissner-Meyerstein, G. Wiedemann, Werner Siemens, E. Dubois-Reymond, Lord Kelvin, Edelmann, F. Kohlrausch, Rosenthal, &c., also with historical remarks, but especially with information as to sensibility. 3. Galvanometers of the latest design. 4. Apparatus for steady mountings and indicating devices. The terms employed by Messrs. Ayrton, Mather and Sumpner for denoting sensibility are recommended for adoption.

**The Electrical Transmission of Sound.**—One of the truly novel features of the Electrical Exhibition in New York was, says our Niagara Falls correspondent, the transmission of the roar of Niagara Falls by telephone. After investigation it was decided that some point near the Cave of the Winds would be the best point at which to gather the sound. Here one can get closer to the falls than at almost any other place. To reach this point, one descends the Cave of the Winds spiral stairway and walks toward the Centre Fall about 200ft. There on the rocky ledge a wooden box, about 3½ft. long, 3ft. high, and 1½ft. wide, was placed. In this box a telephone with a "solid-back" transmitter was placed, and a sheet-iron funnel, 20in. long and about 14in. in diameter at the fall, was fitted to the transmitter. Three standard batteries were placed in the box, but two only were used. About the box white canvas was wrapped to protect the apparatus from the constantly falling spray. At the point where the telephone is placed there are two distinct sounds produced by the falling water. One is a sharp hissing sound, like escaping steam, made by the water as it curls over the rocks below, and goes sweeping out into the river. The other is the deep pounding roar made as the fall strikes the rocks or water below. The first experiments were made with the telephone placed some 12ft. or 15ft. further away from the falling water than was finally the case, and were successful in catching the sharper hiss of the waters. This sound was plainly heard in New York, but the deeper roar was not caught. It was for this reason that a change in location was made, and the roar as heard in the world-famed Cave of the Winds was electrically transmitted to New York, 462 miles distant.

**Repair of the Pouyer-Quertier Cable.**—The Pouyer-Quertier cable, laid in 1879, between Brest and St. Pierre, broke in deep water near the Flemish Cap in June, 1895. Several attempts have been made to effect a repair. First, the cable steamer "Faraday" went out in August last, but although the cable was grappled successfully several times and raised to the surface, a considerable length of new cable being spliced on and laid in, she was compelled to return to England in October, having failed to restore communication. The "François Arago," belonging to the Compagnie Industrielle des Téléphones, next essayed the repair in the winter, leaving Havre early in January. In spite of almost continuous gales and bad weather, she succeeded in getting up the St. Pierre end and buoying it in 563 fathoms. She also got the Brest end in 1,800 fathoms, but lost it again whilst attempting to splice on to it in a heavy sea. Still, every effort was made to recover this end until the middle of March, when a hurricane swept the ship's deck, broke her steering gear, and carried away some of her boats and standing rigging. Having lost nearly all her buoys, ropes and other gear, and having sustained damage to her machinery, she was compelled to suspend further work, and returned to Havre on March 30th, leaving the St. Pierre end buoyed, and a gap of about 30 miles to where the Brest end was lost. During these last operations another break occurred in the cable nearer Brest. The Telegraph Construction and Maintenance Company's ss. "Seine" was then engaged to repair both these breaks, and left Havre on April 29th. Having taken tests from Brest, which made the distance of the break to be 234 miles off, the ship went to that position on May 1st, and hooked the cable the same day, but it broke in lifting. During that and the four succeeding days, the cable was hooked and brought to the bows fourteen times before the repair was finally effected, the cable being very much decayed and breaking every time a short distance from the ship. On May 5th this repair was completed, and the ship made for the western break, arriving at the position (where the "François Arago" had buoyed the end) on May 12th. The weather was rough until May 15th; a careful search was made for the buoy, which, however, was not found; but the position given by the "François Arago" was so accurate that the buoy moorings were hooked on the first drive made by the "Seine," and the end was recovered. The tests proving good to St. Pierre, new cable was spliced on and the end buoyed. On May 17th the Brest end was hooked in 1,800 fathoms, and raised to the bows with a strain of 6 tons on the grapnel. The cable was found good to Brest, and new cable was spliced on and paid out towards the buoyed end. A thick fog necessitated buoying the Brest end before the other buoy was reached. The fog did not clear away until May 21st, when the two buoyed ends were joined up and the repair completed. The "Seine" was ten days occupied on this deep-sea repair, on only four of which was it possible to work.

## RÖNTGEN RAY EXPERIMENTS.

BY PROF. OLIVER J. LODGE, F.R.S.

In continuation of the experiment recorded on page 784 of the issue of April 10th (Vol. XXXVI.) the following facts may be reported:—

A vacuum tube was made with three terminals, two aluminium cups facing each other, and one platinum disc at 45deg. half-way between them, with its terminal coming out at right angles to the other two. Section shown in figure below.

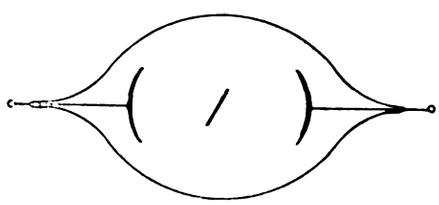
1. The cups being cathode and anode respectively, the insulated platinum disc acted as a moderately weak source, chiefly, of course, on the side facing the cathode. (The other side acts probably only by reason of the partial transparency of platinum.)

2. The platinum being now connected to the cathode, its ray-emitting power practically ceased.

3. The platinum being connected to the anode, it acted as a much more powerful source.

4. Connecting it to the anode through a Wimshurst machine in action, when the machine charged the disc positively it acted as a strong ray source; when the machine was reversed so as to charge the disc negatively it acted as only a very feeble source.

5. Shunting out the machine by short-circuiting its terminals, so as thereby to connect the disc direct to the anode, sometimes improved, sometimes enfeebled, the action. With a low vacuum, such that the induction coil can readily discharge through the tube, the action is best without the Wimshurst; but with a high vacuum, such that the coil has a difficulty in discharging, the intervention of the continuous-action machine greatly improves matters.



In other words, the continuous discharge may be said to maintain a supply of dissociated atoms able to convey the current, and thus dispenses with the heating otherwise frequently necessary.

6. If the machine is interposed between disc and cathode it does good only when it maintains a positive charge on the platinum disc.

7. Without the machine the coil usually acts best when connected so that one cup is cathode and the platinum disc sole anode, so that the charge is concentrated and not shared with any larger surface (though under extra high vacuum conditions a larger anode may become preferable).

8. The addition of the machine, between the disc and the other cup, may readily be made to strengthen the action still further.

9. It is desirable to force up and maintain the positive potential of the platinum disc in every way, *e.g.*, by avoiding any brush discharge or other leak, and by putting the machine in series with the coil when the vacuum gets over high. The usual hasty hook mode of connection for low-vacuum tubes is unsuitable for high vacuum-tubes.

10. When the coil is connected to the two cups, and is in action, the insulated platinum disc in the middle becomes charged, so that a wire attached to it can emit minute sparks The sign of this charge is, in my experience, always positive, no matter how the connection or current be reversed. Doubtless the cause of this is some brush discharge of negative electricity from other terminals; but whatever the cause, the effect is that the disc acquires the positive charge which appears necessary, and is certainly advantageous, to its action as an X-ray source, even when insulated; though, as previously said, it acts better if connected to or made the anode, or otherwise electrified strongly.

So much as a summary of some experiments with this tube. I next pass to a different matter. It has been asserted in France, I believe by M. Lafay, that although the X-rays are not ordinarily affected by a magnet, they become so if they be passed through an electrified plate; as if they were flying particles which could be first electrified and then, of course, magnetically deflected.

This result is profoundly important if true, but I have failed to find it true. Experiments on magnetic deflection are liable to disturbance, owing to the action of a powerful magnet in displacing the cathode rays in even a distant bulb, and so changing the position of the source. My most careful experiments have therefore been made on the *twisting* of rays travelling *along* the lines of magnetic force. For instance, if a Crookes' tube, say the well-known one which casts a shadow of a cross on the glass end, be encased in a helix conveying a current, the shadow of the cross will be notably twisted, and the twist will reverse with the direction of magnetisation. In other words, cathode rays travel spirally along a magnetic field. Do the X-rays the same? Answer, in my experience, they do not: not even when passed through a highly electrified plate first, as in M. Lafay's experiment.

The magnet used was a Faraday magnet with perforated pole-pieces 5·6cm. apart, giving a field, at the middle, of 5,600 C.G.S. lines per square centimetre, when excited for use by 15 or 20 storage cells. At the centre of this field was placed a hemisphere of aluminium with its edges thoroughly protected by an incrustation of molten paraffin, and this was electrified so as to be on the verge of sparking from its convex surface towards one of the poles.

The Röntgen bulb was placed so as to send rays through the tunnel in the first pole-piece, then through the aluminium hemisphere and out at its charged convexity, thence through the 2·8cm. of air magnetised to 5,600 C.G.S., then half-way through the second tunnel, where they encountered a disc of sensitive plate, and impressed themselves upon it.

On the inside of the hemisphere were fixed a couple of parallel copper wires, which the rays encountered before entering the electric field, thereby throwing a shadow of them on the plate. A third wire, parallel to the other two, was fixed in the tunnel (out of either field) close to the plate itself; and when everything was right, on developing the plate, the three shadows came out sharply as three clear parallel lines close together.

The experiment consisted in noting micrometrically whether this parallelism of the shadows was preserved in successive experiments with the electrification or the magnetisation reversed. Not the slightest angular twist of the pair of wires with respect to the single one could ever be seen.

The potential to which the aluminium surface was kept charged was about 40,000 volts, but it is not really a matter of volts, it is a matter of electric density, and this is best specified by saying that it was nearly, not quite, as high as air can stand. It could not be quite as high without risk of the hemisphere giving off an actual spark, which might damage the sensitive plate. Sparks to the pole-piece were obtained *before* inserting the plate, and then the potential was slightly reduced by aid of a safety spark-gap elsewhere. This, which was 2·3cm. wide, was kept sparking during an experiment.

But although the result was thus negative in an electrical field in *air*, it was possible that there might be a positive result in some other medium,—an experiment akin to that of the Faraday magnetic rotation. Accordingly a thick glass plate, 7·3mm. thick, was coated on each side with a small patch of aluminium foil heavily coated all over with slabs of molten paraffin, and the pair of foils were kept electrified. The difference of potential that could thus be maintained across this thickness of glass was much higher than was possible with air, being maintained by a machine which was constantly giving a spark 7·5cm. long between its knobs (2·34cm. diameter), or over 100,000 volts.

This sort of Leyden jar was then placed in the same magnetic field as before, so that the electric and magnetic lines coincided, and the three shadow-throwing parallel wires were again adjusted, two on one side of the glass, and a

Digitized by Google

third, between them, on the other side. The X-rays were now passed through the glass, along the electric and magnetic lines, so as to throw a shadow of the wires on to a sensitive plate (or sometimes on a fluorescent screen); but still no trace of twist could be detected.

Other experiments were made of similar general character, with a greater thickness of air between oppositely charged curved plates, &c., but this record may serve. I conclude, therefore, that until the details of a positive experiment are forthcoming it is apparently not feasible to electrify X-rays by passing them through an electrified surface, whether that surface have a plus or a minus electric density, and whether the medium entered be air or glass.

Mr. Benjamin Davies was my assistant in performing these experiments.

## THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS.*

BY F. C. RAPHAEL.

(*Continued from page 73.*)

**Example VI.**—Ammeter of 10 ohms resistance connected between middle wire and earth; $d_1 = 1{\cdot}38$ ampere. Ammeter is shunted with 10 ohms resistance; $d_2 = 0{\cdot}91$ ampere.

$$\therefore\ F = \frac{1{\cdot}38 - 0{\cdot}91}{1{\cdot}82 - 1{\cdot}38} \times 10 = \frac{0{\cdot}47}{0{\cdot}44} \times 10 = 10{\cdot}7 \text{ ohms.}$$

**Example VII.**—Voltmeter of 300 ohms resistance is connected between middle wire and earth; $d_1 = 3{\cdot}74$ volts. Shunted with 300 ohms resistance; $d_2 = 2{\cdot}54$ volts.

$$F = \frac{3{\cdot}74 - 2{\cdot}54}{5{\cdot}08 - 3{\cdot}74} \times 300 = 269 \text{ ohms.}$$

The fault resistance of a network whose middle wire is permanently earthed through an ammeter of very low resistance can unfortunately not be determined by Methods 2 or 3, owing to the instrument resistance being small compared with the fault resistance to be measured. Theoretically, this does not matter, but the readings and values of the resistances would have to be taken to an impossible degree of accuracy.

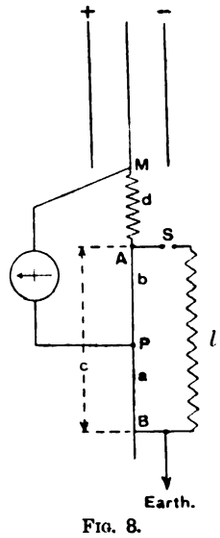


FIG. 8.

*Method 4.* (*Wheatstone's Bridge Method*).—The connections are as in Fig. 8, or 9A and 9B, the point M being connected to the network.

Fig. 8 represents the connections when a bridge of the stretched-wire pattern is used. $d$ is a coil of known resistance; the test is most accurate when this resistance is about equal to the insulation resistance of the network, as then the sliding contact P will, at its balance position, be near the middle of the stretched wire AB. If, however, the insulation resistance of the network be low, $d$ must be chosen of a greater value, as otherwise the stretched wire will be unduly heated by the current flowing through it. The galvanometer should be a fairly sensitive one, and $l$ may be a few lamps connected in parallel. S is a key or switch.

The position of the sliding contact P is adjusted *until the same current flows through the galvanometer whether the contact at* S *is open or closed*, not until no current passes through the galvanometer, as in an ordinary Wheatstone's bridge test. Then the insulation resistance is

$$F = \frac{a}{b} d.$$

If a stretched-wire bridge with two sliding contacts* be used, the bridge is so connected that the end B is the movable end

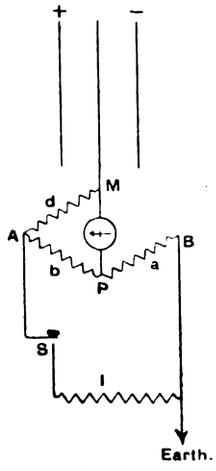

FIG. 9A.

connection and A the fixed one. Then P is fixed at the reading equal to $d$ (or ten times, or one-tenth, or any convenient multiple or fraction of $d$), and the sliding connection B is moved until balance is indicated by the two galvanometer deflections being equal. Then $a$ (that is $c - b$) will give the insulation resistance on the same scale as that on which $b$ represents $d$. When making a measurement just for once in a way this adjustment of the two sliders is not worth the trouble; it is then best simply to fix B at the end of the scale, and to balance by adjusting P, as in an ordinary stretched-wire bridge. But if the apparatus is to be used frequently to test the same insulation resistance it may be a convenience to have it almost direct-reading.

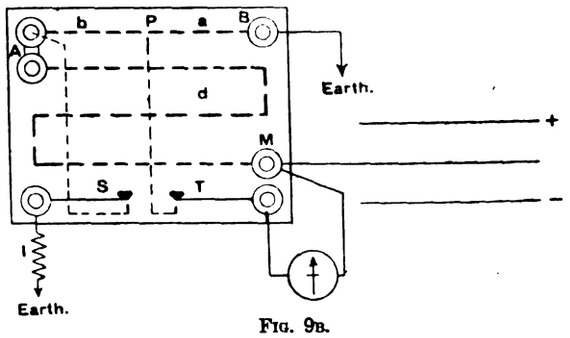

FIG. 9B.

When a bridge of the resistance-box pattern is used for the test we have slightly different conditions. Figs. 9A and 9B represent the connections in this case; Fig. 9A is a "lozenge-shaped" diagram of the bridge, and Fig. 9B shows a Post Office portable pattern bridge connected up for the test. The ratio $b : a$ should be taken as large as circumstances will permit so that $d$ has also to be large, and only a small current passes through the bridge coils. The resistance $l$ may be a few lamps connected in parallel, as before. The key T of the galvanometer circuit must be held permanently depressed, and

* From a forthcoming work to be published by *The Electrician* Printing Publishing Company. All rights are reserved.

* For localising faults, a stretched wire bridge with two sliding contacts has certain advantages. These will be discussed in another place, and suggestions as to the construction of such a bridge will be given.

Digitized by Google

$d$ must be adjusted until the condition of balance is fulfilled—viz., that the same current should pass through the galvanometer, whether the key S is up or down. Then, as above,

$$F = \frac{a}{b} d.$$

There is a possibility, though the case rarely occurs, that the fault resistances on the positive and negative side of the network fulfil the conditions for the potential of the middle wire to be 0, so that no current could be obtained for the bridge when it is connected to the network at the middle omnibus bar. In such a case, point M might be connected to another main instead of to the middle wire, as theoretically the bridge may be connected to any point of the network. But in practice it is to be preferred to leave M connected to the middle 'bus bar, and to insert a battery of a few cells in series with $l$; this avoids the danger of too large a current passing through the coils or stretched wire of the bridge. If the deflection of the galvanometer is to the end of the scale before the key S is depressed, this deflection must be reduced by shunting the instrument either with a resistance coil or with a length of fine wire; or else, if the current causing the deflection is not very large, and the instrument is not of the d'Arsonval type, the needle may be brought back to zero by moving the controlling magnet, or by placing another magnet near to the instrument in such a position as to neutralise the effect of this current.

*General Conclusions and Comparison of Methods 1 to 4.*

Whatever method be employed, it is always advantageous to have a high-resistance recording voltmeter permanently connected between one (or each of) the outer mains and earth. Besides indicating the nature of faults, as already explained, it also gives a clue to which of the mains is faulty, and acts as a sort of check on the daily insulation test. A substitute for this is a high-resistance or electrostatic voltmeter, from which readings are noted every hour by the switchboard attendant.

Of the four methods described, No. 4 is undoubtedly the most accurate, but it has the disadvantage of giving no indication of the relative fault resistances of the mains. It is true that if a recording voltmeter be employed one can see whether a fault has occurred on the positive or negative side of the network; but it requires some judgment, and there is always some uncertainty as to whether the fault is on the middle wire or on the outer wire. There is just the general rule to go by, that a drop in the insulation resistance effects more change in the absolute potentials of the mains (*i.e.*, in the difference of potential between each main and earth) if it occurs on the outer wire than if it occurs on the middle wire. The same rule is a guide in the case of a five-wire network. A fault in one of the extreme mains affects the absolute potentials more than the same fault would had it occurred in the adjacent main; and much more than it would had it occurred in the middle wire. For three and five-wire networks, therefore, Method 4 may be used occasionally to measure the insulation resistance accurately, but one of the other methods should be used for the daily test. For two-wire networks the above objection to Method 4 does not hold, as, by connecting almost any voltmeter or ammeter momentarily between each main and earth, it is immediately apparent on which main the fault is. The connections of the bridge are not terribly complicated, though it is well to refer to the diagram the first time they are made.

Some central-station engineers have an unconquerable objection to momentarily increasing the leakage from one of their mains, especially from one of their outer mains. Then the choice of methods is very limited, and in many cases an accurate test is out of the question. Method 2 is then the best test to choose, but in some instances mentioned it would be necessary to use adjustable resistances of known value and capable of standing moderately strong currents; such coils are costly and decidedly a luxury. Method 1 may be used with voltmeters of fairly high resistance; the disadvantages of this method, when the resistance of the voltmeter is high compared with the insulation resistance of the network, have already been pointed out. Method 3 is also not sensitive under these circumstances.

In most cases Method 3 is the test to be recommended. It is not quite so sensitive as Method 1, but it has the advantages of partially earthing the middle wire only, and of needing an instrument with a much shorter range than that required for Method 1. Where the fault resistances of the mains are so balanced that no current is ordinarily to be obtained between the middle wire and earth, it is perhaps preferable to use Method 1 than to complicate Method 3 by the introduction of an artificial fault.

Method 1 has the advantage of being the oldest method and the one most used hitherto. It was first employed in Vienna by Mr. Gustav Frisch in 1889, and is at present used daily at several central stations, including the Westminster and Liverpool stations, both of which employ low resistance ammeters for the test.

It should be mentioned that, in all tests described, the insulation resistance that is measured is in reality the insulation resistance of the network, generating plant, switchboard, &c., in parallel. In well-managed stations the normal earth-leakages from the latter are nothing compared to the earth-leakage from the network, and if an earth occur in a dynamo or in the battery room it is at once detected.

It is always advisable to insert fuses between the mains and the testing instruments. The resistance of the fuse always being insignificant compared with the fault resistance of the main, it need not be allowed for.

As before stated, ammeters and voltmeters giving readings to both sides of zero are the most convenient to use. Some instruments give readings to one side only, but are provided with an extra pointer, which indicates in which direction the current is flowing; these, of course, answer the same purpose. Other types will only measure currents flowing through them in one direction; such instruments are inconvenient to use for these tests.

*Alternating Current Low-Pressure Networks.*

The four methods as above described are not suitable for measurements on alternating current networks. Method 4 may, however, be used, if a galvanometer is chosen that will not deflect for alternating currents, by putting a few battery cells in the arm $l$. A fuse should be inserted at M or B, or both, to protect the slide wire or bridge coils; and the galvanometer circuit between M and P should also include a delicate fuse.

The daily test of such networks should be the measurement of the potential difference between each main and earth; this test will give a comparative indication of the condition of the network from day to day, but will not enable one to calculate with accuracy its insulation resistance. The reader is referred to the remarks on the value of the potential of the respective mains in the article on high-pressure networks which follows.

*(To be continued.)*

## PATENTS IN 1895.

In his Thirteenth Report the Comptroller General of Patents states that in 1895, for the first time since the year 1885, the number of applications for patents showed no increase upon that of the preceding year, but, on the contrary, a decrease of 321. This decrease, however, was entirely due to a falling off of 676 in the number of applications accompanied by *provisional* specifications, those accompanied by *complete* specifications having increased, in even more than the usual proportion, by 355; 2·3 per cent. of the total number of applications were made by women. Six applications were made to the Privy Council for extensions of patents—of these, three applications were refused, two applications were withdrawn, and one case remained undecided. The number of readers frequenting the Patent Office Library during the year was 108,285, or a decrease of 5,089 as compared with the previous year.

The total receipts of the Patent Office for the year ending December 31, 1895, amounted to £187,012, as against £182,000 for the preceding year. Of this sum £168,428 was

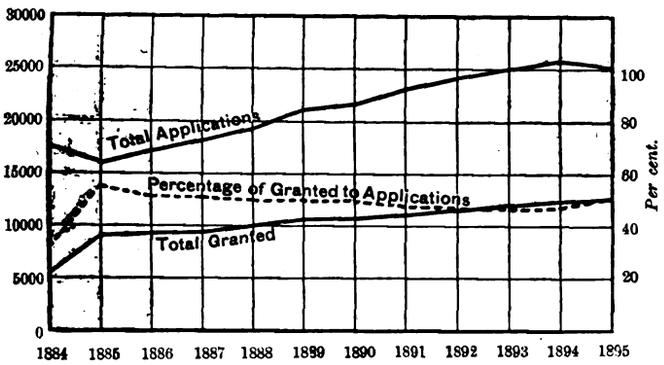
derived from patent fees. The expenditure last year amounted to £100,671, against £96,000 for the year 1894. A surplus of £86,341 was thus realised by the operation of the Patent



Curves showing total number of Patents applied for each year since 1884, also percentage ratio of Patents granted to Patents applied for, and total number of Patents granted.

Office during 1895. The two principal items of expenditure were—salaries, £54,853, and printing £24,650. The sum of £10,161 was expended on new works.

## THE EVOLUTION OF MODERN SCIENTIFIC LABORATORIES.*

BY PROF. W. H. WELCH.

The scientific discoveries of the present century have had such a profound influence upon inventions, upon industries, and upon the comfort, health, and welfare of the people in general, that there is widespread, even if not always adequate, appreciation of the value of scientific study and investigation. But it may be doubted whether there is any proper understanding, in the minds even of the educated public, of the material circumstances which surround scientific discovery, and which make it possible. The average man, if interested at all, is interested that the discovery is made, not how it is made. In America, where men of science rely mainly upon enlightened private beneficence, and not upon governmental aid, to furnish the pecuniary resources which are essential for scientific progress, it is important that there should be some general information, not only regarding the results of scientific work, but also regarding the external material conditions necessary for the fruitful prosecution of such work.

At the present day the systematic study and advancement of any physical or natural science requires trained workers who can give their time to the work, suitably constructed work-rooms, an equipment with all of the instruments and appliances needed for the special work, a supply of the material to be studied, and ready access to the more important books and journals containing the special literature of the science. All of these conditions are supplied by a well-equipped and properly organised modern laboratory. Such laboratories are, with the partial exception of the anatomical laboratory, entirely the creation of the present century, and for the most part of the last fifty years. They have completely revolutionised during the past half century the material conditions under which scientific work is prosecuted. They are partly the result, and in larger part the cause, of that rapid progress of the physical and natural sciences which characterises the era in which we are living.

The evolution of the modern laboratory still awaits its historian. It is not difficult to find incidental references to historical facts bearing upon this subject. The development of the chemical laboratory has been traced with some fulness. But it is curious that there is no satisfactory monographic treatment of the general subject of the historical development of scientific laboratories. The subject seems to me an attractive one. It would surely be interesting to trace the development of the teaching and the investigating laboratory back to its beginnings, to learn about the material circumstances under which the physicists, the chemists, the morphologists, and physiologists of former generations worked. What share in the development of laboratories had the learned academies of the Renaissance and of the subsequent centuries? What share had public and private museums and collections of instruments of precision? What share had the work of the exact experimentalists, beginning with Galileo, of physicians, of the alchemists, and of the apothecaries? What individuals, universities, corporations and governments were the pioneers in the establishment of laboratories for the various physical and natural sciences? The detailed consideration of these and many other questions pertinent to the subject would make an interesting and valuable historical contribution.

There is evidence that in Alexandria, under the early Ptolemies in the third century before Christ, there existed state-supported institutes, in which students of man and of Nature could come into direct personal contact with the objects of study, and by the aid of such appliances as were then available could carry on scientific investigations. The practical study of anatomy, physiology, pathology and other natural sciences was here cultivated. We are very imperfectly informed as to the results and the material circumstances of this remarkable period in the history of science. We know that after about a century of healthy activity the Alexandrian school gradually sank into a place for metaphysical discussions.

Fifteen hundred years elapsed before we next find any record of the practical study of a natural science. In 1231 the great Hohenstaufen, Frederick the Second, who has been called the most remarkable historic figure of the Middle Ages, commanded the teachers at Salernum diligently to cultivate the practical study of anatomy. After the passage of this edict occasional dissections of the human body were made, but it cannot be said there was any diligent cultivation of anatomy on the part either of teachers or of students during the following two centuries. In the latter half of the fifteenth century there developed that active interest in the practical study of human anatomy. For over 600 years there has been at least some practical instruction in anatomy, and for over 300 years there have existed anatomical laboratories for purposes of teaching and of investigation, although only those constructed during the present century meet our ideas of what an anatomical laboratory should be. It is a matter of no little interest, both for the history of medicine and for that of science in general, that the first scientific laboratory was the anatomical laboratory. Private laboratories for investigation must have existed from the earliest times. Doubtless Aristotle had his laboratory. But the kind of laboratory which we have on this occasion in mind is one open to students or investigators, or both. There was no branch of physical or natural science, with the exception of anatomy, which students could study in the laboratory until after the first quarter of the present century. Only in anatomy could students come into direct contact with the object of study, and work with their own hands, and investigate what lay below the surface.

The famous Moravian writer on education, Amos Comenius, over 250 years ago, gave vigorous expression to the conception of living, objective teaching of the sciences. He said: "Men must be instructed in wisdom so far as possible, not from books, but from the heavens, the earth, the oaks and the beeches—that is, they must learn and investigate the things themselves, and not merely the observations and testimonies of other persons concerning the things." "Who is there," he cries, "who teaches physics by observation and experiment, instead of by reading an Aristotelian or other text-book?" But how little ripe were the conditions then existing for the successful carrying out of ideas so far in advance of his times is illustrated by the very writings of the author of "Orbis Pictus" and "Lux in Tenebris."

It would lead too far afield to trace in detail on this occasion the development of physical and of chemical laboratories, but a few words on this subject will not be out of place. Methodical experimentation in the sciences of Nature was definitely established by Galileo, and was zealously practised by his contemporaries and successors in the seventeenth century. It was greatly promoted by the foundation during this century of learned societies, such as the Academia dei Lincei and the Academia del Cimento in Italy, the Collegium Curiosum in Germany, the Académie des Sciences in Paris, and the Royal Society in England. Much of the classical apparatus still employed in physical experiments was invented at this period. Experimental physics from the first acquired a kind of fashionable vogue, and this aristocratic position it has ever since maintained among the experimental sciences. These sciences must concede to physics that commanding position which it has won by the genius of the great natural philosophers, by the precision of its methods and the mathematical accuracy of its conclusions, and by the fundamental nature and profound interest and importance of its problems. The debt of the medical sciences to the great experimental physicists, from Kepler and Galileo and Newton down to Helmholtz is a very large one.

There existed in the last century cabinets of physical apparatus to be used in demonstrative lectures, but they were very inadequate, and suitable rooms for experimental work scarcely existed. It was not until about the middle of the present century that we find the beginnings of the modern physical laboratory. Lord Kelvin, then William Thomson, established a physical laboratory in the University of Glasgow about 1845, in an old wine cellar of a house. He

* Abstract of an address delivered at the opening of the William Pepper Laboratory of Clinical Medicine, Philadelphia, December 4, 1895.

Digitized by Google

tells us that "this, with the bins swept away, and a water supply and sink added, served as a physical laboratory for several years." It was as late as 1863 that Magnus opened in Berlin his laboratory for experimental physical research. Since 1870 there has been a rapid development of those splendid physical institutes which are the pride of many universities.

Humbler, but more picturesque, was the origin of the chemical laboratory. This was the laboratory of the alchemist searching for the philosopher's stone. In the painter's canvas we can still see the vaulted, cobwebbed room with its dim and mysterious light, the stuffed serpent, the shelves with their many-coloured bottles, the furnace in the corner with the fire glowing through the loose bricks, the fantastic alembics, the old alchemist in his quaint arm-chair reading a huge, worm-eaten folio, and the assistant grinding at the mortar. Fantastic and futile as it all may seem, yet here was the birth of modern chemistry. The alchemists were the first to undertake the methodical experimental investigation of the chemical nature of substances. No more powerful stimulus than the idea of the philosopher's stone could have been devised to impel men to ardent investigation. But search for gold was not all that inspired the later alchemists. Paracelsus, the alchemist, said, "Away with these false disciples who hold that this divine science, which they dishonour and prostitute, has no other end but that of making gold and silver. True alchemy has but one aim and object—to extract the quintessence of things and to prepare arcana, tinctures and elixirs which may restore to man the health and soundness he has lost." And again he says of the alchemists: "They are not given to idleness, nor go in a proud habit or plush or velvet garments, often showing their rings upon their fingers, or wearing swords with silver hilts by their sides, or fine and gay gloves upon their hands, but diligently follow their labours, sweating whole days and nights by their furnaces. They do not spend their time abroad for recreation, but take delight in their laboratory. They wear leather garments, with a pouch and an apron wherewith to wipe their hands. They put their fingers among coals and into clay, not into gold rings."

During the seventeenth and eighteenth centuries the doctrines and work of the alchemists had profound influence upon medicine. Alchemy was not completely overthrown until Lavoisier gave the death-blow to the phlogistic theory of Stahl. But for a considerable time before Lavoisier introduced the new spirit into chemistry its methods and its problems were gradually approaching those of modern times. It was, however, over thirty years after the tragic death of Lavoisier before the first chemical laboratory in the modern sense was established. One cannot read without combined feelings of wonder and pity of the incommodious, forlorn, and cramped rooms in which such men as Scheele and Berzelius and Gay-Lussac worked out their memorable discoveries. Liebig has graphically described the difficulties encountered by the student of that day who wished to acquire practical training in chemistry. With some of the apothecaries could be obtained a modicum of practical familiarity with ordinary chemical manipulations, but Sweden and France were the centres for those with higher aspirations.

It was the memory of his own experiences which led Liebig, immediately after he was appointed professor of chemistry in Gissen in 1824, to set about the establishment of a chemical laboratory. Liebig's laboratory, opened to students and investigators in 1825, is generally stated to be the first modern public scientific laboratory. Although, as we shall see presently, this is not quite correct, it is certain that Liebig's laboratory was the one which had the greatest influence upon the subsequent establishment and organisation not only of chemical laboratories, but of public scientific laboratories in general. Its foundation marks an epoch in the history of science and of scientific education. This laboratory proved to be of great import to medical science, for it was here, and by Liebig, that the foundations of modern physiological chemistry were laid. The significance of this memorable laboratory of Leibig is not that it was a beautiful or commodious or well-equipped laboratory, for it possessed none of these attributes—indeed, it is said to have looked like an old stable—but that here was a place provided with the needed facilities, and under competent direction, freely opened to properly-prepared students and investigators for experimental work in science.

The chemical laboratories of to-day are, in general, the best organised and the best supported of scientific laboratories. The need of establishing physiological laboratories was recognised several years before the foundation of Liebig's laboratory. The important results to be derived from the application of the experimental method to the study of vital phenomena had been demonstrated first and most signally by Harvey, and after him by many experimenters. The fecundity of exact experimentation by physical and chemical methods applied to the phenomenon of life had been shown by the classical researches of Lavoisier on respiration and animal heat. Magendie had entered upon that remarkable scientific career which entitles him to be regarded as the founder of modern experimental physiology, pathology, and pharmacology. With two or three exceptions, all of the separate physiological laboratories worthy of the name have been established since the middle of the present century. Bernard, that prince of experimenters, worked in a damp, small cellar, one of those wretched Parisian substitutes for a laboratory which he has called "the tombs of scientific investigators." There can be no greater proof of the genius of Bernard than the fact that he was able to make his marvellous discoveries under such obstacles and with such meagre appliances. France was long in supplying her scientific men with adequate laboratory facilities, but no more unbiassed recognition of the value and significance of the German laboratory system can be found than in the reports of Lorain, in 1868, and of Wurtz, in 1870, based upon personal study of the construction and organisation of German laboratories.

It is apparent, from the brief and imperfect outline which I have presented of the evolution of modern scientific laboratories, that the birthplace of these laboratories, regarded as places freely open for instruction and research in the natural sciences, was Germany. Such laboratories are the glory to-day of German universities, which possess over two hundred of them. By their aid Germany has secured since the middle of the present century the palm for scientific education and discovery. Great scientific investigators are not limited to any country or any time. There are those of surpassing ability who will make their own opportunity, and will triumph over the most discouraging environment. This country and every civilised country can point to such men, but they are most exceptional. The great majority of those even with the capacity for scientific work need encouragement and opportunity. We now have sufficient knowledge of the workings of scientific laboratories to be able to assert that in general where the laboratory facilities are the most ample and the most freely available, there are developed the largest number of trained workers, and there the discoveries are the most numerous and the most important. At the present day no country, no university, and no medical school can hold even a respectable place in the march of education and progress unless it is provided with suitable laboratories for scientific work.

A properly equipped and properly conducted scientific laboratory is a far more expensive institution than is usually conceived. It must be suitably domiciled either in a separate building or in rooms commodious and well lighted. The outside architectural features are of secondary importance. The instruments and appliances necessary for exact observation and experiment, even in those sciences which apparently require the least, are numerous and costly. A working library, containing the books and sets of journals most frequently consulted, is most desirable, if not absolutely indispensable. The director of the laboratory should be a man of ability and experience, who is a master in his department of science. He must have at least one assistant, who is preferably a young man aiming to follow a scientific career. A person of no small value in the successful working of the laboratory is the intelligent janitor or "diener," who can be trained to do the work of a subsidiary assistant, and can be entrusted with the care and manipulation of instruments. There must be funds for the purchase of fresh supplies and new instruments when needed. The running expenses of a first-class laboratory are not small. But, costly as may seem the establishment and support of a good laboratory, the amount of money expended for laboratories would seem to us ridiculously insignificant if we could estimate the benefits to mankind derived from the work which has been done in them. Wurtz has truly said of the money required for laboratories, "It is a capital placed at a high rate of interest, and the comparatively slight sacrifice imposed upon one generation will bring to following generations increase of well-being and knowledge."

The educational value of the laboratory cannot well be overestimated. For the general student this is to be found primarily in the development of the scientific habit of thought. He learns that to really know about things it is necessary to come into direct contact with them and study them. He finds that only this knowledge is real and living, and not that which comes from mere observation of external appearances, or from reading or being told about things, or, still less, merely thinking about them.

## THE DEVELOPMENT OF ELECTRICAL TRACTION APPARATUS IN THE UNITED STATES.*

BY H. F. PARSHALL.

In this Paper I propose to discuss and illustrate the more important details of the machinery especially developed for use in electrical traction. At the commencement of my experience, about six months was taken to construct 40 street car motors. At the present day, in the same works, there are constructed regularly 150 street car motors per week, and, in some cases of extreme demand, as many as 500 have been constructed in the same length of time.

* Abstract of a Paper read before the Society of Arts, February 18th, 1896.

Digitized by Google

The difficulties experienced with the apparatus as first designed were largely confined to the motor and motor regulator, this latter being now commonly called the controller. After these had been brought into a better state of perfection, refinements were introduced in the power station and in the switching appliances. This being the order of development, it will also be taken as the order for discussion.

The tramway motors first constructed in the United States were but little suited for the work of electrical traction. Engineers but little understood the great strain, both mechanical and electrical, to which this machinery would be subjected. In general, the motors were designed on much the same lines as central station dynamos and stationary motors had previously been. The speed and the torque at different speeds of the motors, in general, did not agree with the speed and resistance of the car at different speeds. Special attention was paid to the efficiency at full load, but, inasmuch as the mean working point was much less than the full load of the motor, efficient results were not obtained until power measurements as to the average work required for the propulsion of a car were made, and the motor so designed that the efficiency was towards a maximum at the average working point of the motor.

Another point that was not clearly recognised related to the torque per ampere best suited to such a motor. In starting the car, the torque per ampere should be a maximum. As the car becomes accelerated, the torque per ampere should be less, and should fall off according to the maximum speed to be attained. In the first motors the torque per ampere, owing to the proportions of the motor, was approximately constant, so that an excessive starting current was required, this being so great that, frequently, there was great heating of the windings, and the durability of the motor was greatly impaired. At the present day, in well designed street car motors, the effort at the car wheel is about forty pounds per ampere in the armature, and, when running at full speed, from twenty to twenty-five pounds. In thus varying the range of torque per ampere the efficiency of the motor has been increased, and, likewise, the durability of the parts in which the electrical losses occur.

The mechanical improvements found necessary to make were numerous and important. The diameter of the shaft had to be increased so that the factor of strength was some six times greater than in ordinary station motors and dynamos; the bearings had to be increased in length and diameter; and the face of the gear had to be increased, and also the pitch. The fine pitch that had previously been found satisfactory in machine construction was found to be altogether unsuited for tramway motors. Improvements were also made in the method of holding the armature conductors, since it was found that the conductors, when held in the ordinary way, would shift in respect to each other, and so injure the insulation as to impair the durability of the armature.

In order to lessen the deterioration of the controlling mechanism, which was either a commutating switch or a rheostat, it was found necessary to design the motor so that the torque per ampere, at a given speed, coincided with the resistance of the car for a given acceleration and speed. Increasing the efficiency of the motor, that is, lessening the amount of current for which a given torque and acceleration is produced, greatly lessened the deterioration of the controlling apparatus, so that advancement in the design and efficiency of the motor was accompanied with a corresponding durability of the controlling apparatus.

The next more important step in this direction was the substitution of the multipolar motor and the dispensing with one set of gears. This was found practicable, when the manufacture of steel had advanced so that castings of high permeability, and of the complex form required for tramway motors, could be made. The earlier types of motors were made of forgings of simple shape, which were not of such form as could be made into multipolar motors. This last change was accompanied by numerous other mechanical improvements. The gears, shaft and bearings were again increased in size. The method of lubrication was improved, the gears being placed in an oil-tight box, so that their durability was increased some three or four times. A steel gear will now wear for three years and a pinion nine months, in an equipment making 100 miles a day. The pinions usually have 13 to 16 teeth and the gear from 60 to 70. The pitch commonly used is that known, in the United States, as the No. 3 pitch, *i.e.*, the diameter of the gear divided into the number of teeth=3. By making the shaft more rigid, and by studying the form and clearance of the teeth, a gear has now been produced that makes comparatively little noise.

Another improvement relates to the method of suspending the motor in the so-called "nose-suspension" manner, in which the motor is carried by a lug and cross bar. The top axle lining lasts about six months, and the bottom axle lining about twelve months. *With the side bar suspension*, in which the motor is suspended in a line vertically underneath its centre of gravity, the axle linings last twice as long.

Great mechanical improvements have also been made in the construction of the commutator, which is subjected to hard usage, owing to the necessity of carbon brushes (set at a very considerable pressure on account of the vibration of the motor). A well constructed commutator may now be expected to last two years.

A further improvement has been to completely house the motor in a steel casing so that it is now entirely waterproof. The force with which water penetrates a tramway motor in a wet street is remarkable, since the joint between the upper and lower halves of the motor have to be especially larded to keep the water from oozing through even when the surfaces are as perfectly milled and fitted together as possible.

The electrical features of the motor have also received decided mechanical improvement. The armature coils are formed and interchangeable, and insulated, first with abestos, and, secondly with mica and tape, so that it will withstand a very high temperature. The method of securing the armature coils has also formed the subject of study and improvement. The coils are now held upon a conical surface, and securely clamped by a nut so that any shifting is prevented.

Another improvement is in reference to the magnet coils, which are insulated with asbestos, and made entirely waterproof. It would seem perhaps that this was unnecessary, considering that the motor itself was made waterproof, but condensation of water frequently occurs in an encased motor, and renders it necessary for good results that both the coils of the field and of the armature should be waterproof.

Another improvement that has been found of great importance in practice is the diminution of the weight of the motor for a given power. This has been done by the use of steel, and by studying, particularly, the mechanical construction, and the nature of the work to be done. A motor nominally rated as 25 H.P., complete with the gearing, now weighs about 1,500lbs. Such a motor cannot, of course, do 25 H.P. permanently, but it is rated on its capacity for doing this work for a limited period of time—generally two hours—this being a more satisfactory manner of rating for electrical traction. With this diminution of weight it has been found that the deterioration of tracks, trucks and bearings, has been greatly lessened. Great improvements have also been made in the construction of trucks for tramway purpose.

The motor that has heretofore been illustrated, and particularly discussed, is what is known as the "standard tramway motor," *i.e.*, a motor capable of exerting 800 to 1,000lbs. horizontal effort on the car wheel, when running 10½ miles per hour and delivering 25 H.P., when mounted on 33in. wheels and loaded to its rated capacity. It differs only in the point of size from the larger motors that are used in what may be termed "light railways," along which trains, weighing from 60 to 100 tons, are moved at a speed of 15 to 45 miles an hour, and, in some cases, to 60 miles an hour.

In the standard motor the diameter of the car axle is 3⅜in., the pinion is seated with paper bore, the axle gear is of cast iron, and the gear reduction is 4·78 to 1. This motor is suited for all ordinary city tramways. It has been frequently wound for a higher speed and different output, but the consumption of energy in a given time is increased according to the increase of speed, that is, the consumption of energy per car mile in a given motor remains practically the same so long as the magnetic conditions remain constant. In high speed or suburban railway work, where heavy grades and heavy loads have to be met with and drawn from 20 to 30 miles an hour, a motor having a rated horizontal effort of 1,200lb. when running 12 miles an hour and delivering 40 H.P. under the previously-mentioned conditions is commonly used. For a still heavier class of work two or four motors are used per train, each giving 2,000lb. horizontal effort when running 20 miles an hour and delivering approximately 120 H.P. under the previously-mentioned conditions. Two such motors will operate three ordinary passenger cars at a speed of 30 to 40 miles an hour, and four of them operate six passenger cars. It is interesting to note that, in the design of these motors, the maximum rated horizontal effort is not varied by varying the number of turns on the armature so long as the weight of the copper and the magnetic flux remain the same. I give herewith a table that shows the general results and traction coefficients that have been obtained in the United States with the forms of equipment with which I am familiar.

Referring next to the controller, I may state that this has undoubtedly required as much attention and invention to perfect as the motor. The controller now generally used is known as a series-parallel controller—*i.e.*, the motors are started in series with each other. This lessens the starting current for a given horizontal effort to half of that when the motors started together in parallel. It has been found that, in cities where the number of stops are frequent, by the use of the series-parallel controller, the consumption of energy per car is lessened 40 per cent. Of course, there would no such gain in suburban districts where the stops are less frequent.

The different steps gone through in the starting of two motors by the series-parallel method are as follows:—

The two motors are started in series and with an external resistance, which is gradually turned out of circuit. One of the motors

is shunted with a varying resistance until short-circuited. It is then open circuited, with respect to the other motor, and, by means of varying resistances, the motor is finally brought into parallel with the second motor.

The most salient features of the developed controller are as follows:—Magnetic blow-out, placed wherever the circuit is to be broken, and which practically eliminates the burning of the contacts and greatly increases their durability; copper contacts used instead of brass contacts, it having been found that brass is less durable. Separate cut-out switches are used, so that either motor may be cut out of circuit at the will of the operator. An interlocking reversing switch is used so that motors can only be reversed when the current is turned. Safety braking switches are placed on the reversing switch, so that, in case of emergency, the power may be turned off and the motors short-circuited, so that they act as generators, in which case the car is speedily brought to a standstill. This method of braking is what is known as the emergency method, since it is not suitable for general use on account of the great strain put upon the motors.

A method that is coming into use in the United States is that of connecting the motors, with their fields reversed, through the coils of a magnetic brake. This is effected from the main handle of the switch and the braking power regulated according to the position of the controlling cylinder.

Many of the features above mentioned in connection with the standard type of controller are incorporated in the controllers for the larger motors, but, owing to the greater contact surface, and the greater amount of friction, special means have to be provided for turning the cylinder. In some controllers for four motors two separate switches are used, the two being operated by a single shaft by means of gears.

Referring next to the progress made in electrical locomotives, I will call your attention to a locomotive recently constructed by the General Electric Company of America for the Baltimore tunnel of the Baltimore and Ohio Railway. The particulars of this locomotive are as follows:—Number of trucks, 2; number of motors, 4; weight of driving wheels, 192,000lb.; number of driving wheels, 8; drawbar pull, 42,000lb.; starting drawbar pull, 60,000lb.; gauge, 4ft. 8½in., and diameter of driving wheels, 62in.; length over all, 35ft.; height to top of cab, 14ft. 3in.; wheel base of each trunk. 6ft. 10in.; extreme width, 9ft. 6½in.; diameter of sleeve bearings, 13in. On this locomotive the particular form of overhead construction is worthy of notice. It consists of a shoe in an inverted channel. It was first intended to use the ordinary trolley, but it was found that the current density was too high for this work. The motor of this locomotive has a rated output of some 300 H.P., and may be reversed at full load without any sparking at the brushes. The armature is, in this case, series wound. The fields are of six poles, three of them being long and carrying the larger magnet coils (this being made necessary on account of the space in which the motor has to be put), and three of the poles being shorter. These poles are wound with a number of turns consistent with the armature reaction. The thought will probably come to some as to whether or not it is necessary to put coils on these poles. I will state that it is, and that the construction shown is the best, since specific experiment has shown that the distribution of the field is better, and, likewise, the tendency to spark is greatly lessened, when all the poles of such a motor are excited. The armature is constructed on a hollow sleeve, the internal diameter of which is some 2in. greater than the diameter of the axle. Motion is transmitted from the armature to the axle by means of a spider carried on a hollow sleeve, the extremity of the arms of this spider engaged with cushioned lugs carried the locomotive wheels. This construction removes the dead weight of the motor from the axles and transmits it through the springs of the trucks. This is a great advantage, mechanically, in preventing hammering on the rails, and also a great protection to the windings of the motor from shock. A locomotive thus driven is remarkable for its smoothness and quietness in running.

* 20lb. per ton for 11 ton train.

† 15lb. per ton for 30 ton train. 10lb. per ton for 120 ton train. The output required by train on a level will vary within wide limits, with cars of varying weights and track in varying conditions.

Both the electrical and mechanical problems involved in the construction of such locomotives are most difficult, but the experience has been ample to show that they have been fairly met and that a successful and, in all ways, satisfactory electric locomotive has been produced. The magnetic densities in the air gap of such a machine and in the projections have to be extremely high, being from 80,000 to 90,000 C.G.S. lines per square inch in the air-gap, and from 150,000 to 180,000 C.G.S. lines per square inch in the projections, not allowing for the leakage between them, which is of course considerable.

Turning next to the appliances in the station, I would say that these also have been subjected to great improvement. Perhaps the most noticeable improvement is that of the substitution of direct connected generators for the belt-driven machinery at first used, and I may here state that I do not consider large belt-driven dynamos suitable for electric traction work. The average work is greatly below the maximum work, if the driving belt is given sufficient tension to avoid slipping at the maximum load, the loss in the bearings is excessive for the average load. This objection, however, is entirely secondary to the mechanical objections of a belt connecting an engine with a dynamo subject to rapidly fluctuating loads. The largest belt-driven dynamo that has been constructed in the United States is of 500 kilowatts output. The use of this machine is, however, becoming exceptional. The trouble experienced with the bearings, together with the considerable floor space and the greater cost of the machine as a whole, with no compensating feature in its operation, has led to the substitution of direct connected machines. From 150 kilowatts capacity and larger, the belt-driven dynamos should not be used. In the extreme case, dynamos of not more than 200 kilowatts capacity should not be driven by belts or ropes.

At the Exposition in Chicago was exhibited a machine of 2,000 E.H.P. output, designed by me. The specification for this machine was that it should not heat more in any part than 30° C, should be subjected to variations of load, equal to its rated capacity, without sparking, and should carry 50 per cent. overload without dangerous heating or sparking. Owing to the short time at the disposal of the makers, the dynamo was first assembled and tested in Chicago, and was found to perfectly comply, in all respects, with the specification. The diameter of the armature is 10½in., diameter of commutator 7ft., number of segments 696, length of commutator 18in., field magnets 12 poles, magnet frame constructed of steel, the use of steel being found most economical. The construction of the commutator is worthy of special attention, the segments being held so as to equally expand along their length, and in such a manner that different parts of the commutator may be taken out without disturbing the remaining parts. Eleven of these machines have now been constructed from the original designs, and are working satisfactorily in the United States. Numerous smaller machines have also been constructed. In the commutator of the 1,500-kilowatt machine there are 7,000lb. of copper. The weight of the armature is 86,000lb., and the weight of the machine complete is 180,000lb. The design of these machines to a given specification required very considerable study, both as to the density of the air-gap, the armature reaction and the number of commutator segments; this problem has been accurately solved.

The transmission of power to a distance by means of multiphase currents and the distribution by means of motor-generators, and by so-called rotary converters (which is a machine running as a synchronous motor but with closed circuit armature windings, the conductors being arranged so that commutation is effected) is now receiving considerable attention. The source of power at Portland, U.S.A., is from turbines. The shaft is vertical and the weight of the armature is carried by a hydraulic bearing. The current is generated at a pressure of 6,000 volts and at a frequency of 33. This frequency is as high as the use of large rotary converters used in the sub-stations will permit. On account of the problems connected with the commutation of the currents the maximum size of a rotary converter is limited to the periodicity, *i.e.*, for comparatively high periodicities only rotary converters of small output can be constructed.

In a sub-station are operated two 500-kilowatt rotary converters, the current being transformed down to suit the E.M.F. in the rotary converter. The ratio of the three-phase voltage to the continuous voltage of the machine is fixed by the extent of pole arc of the field magnets. The ratio is generally about 0·612. It may, however, be varied by varying the percentage of the pole arc of the field magnets. Experience with such machines shows that best results are secured when the currents are delivered in phase with the E.M.F. Either a lagging or leading current with respect to the E.M.F. of the rotary converter occasions more or less sparking. The distribution of the current among the armature conductors is a fit subject for a mathematical investigation, since the armature receives energy in the form of alternating currents, and delivers energy in the form of continuous currents. An examination as to the current distribution in a commutating machine with that of the current distribution in a synchronous motor, under many conditions, shows that the average

Digitized by Google

effective current strength in the armature conductors is less than would be inferred from a separate examination of each. Thus, under some conditions of running it is found that the cross section of the conductors in such machines may be less than those of an ordinary commutating machine or of an ordinary synchronous motor. An investigation of the properties of this machine was recently carried out at Niagara Falls by me and other engineers of the General Electric Company of America. It was found, however, that owing to the condition of supply and the nature of the currents, that is, quarter phase currents, the feature was but of little importance in practice.

Recently I have designed the multiphase system for the distribution of power to electric tramways in Dublin. The object of the use of the three-phase in this particular case is to comply with the Board of Trade requirements as to the drop of voltage in the earth return. In this case I have preferred to use synchronous motors driving commutating machines, the particular advantage in this being that the phase of the current, in respect of the E.M.F., may be regulated by the excitation of the synchronous motor. In the case of the rotary converter this may not be done without varying the pressure in the consumer's circuit. There is also, in my opinion, some advantage in the use of a synchronous motor over an ordinary static transformer, the one being more easily repaired, and less liable to give way under the overloads that are frequent in tramway systems. It is not necessary to mention that the three-phase system is only used as a convenient means of transmitting power at a high tension. The three-phase synchronous motors have the advantage of being self-starting, and there is also another advantage in that the amount of copper required is about three-quarters of that required in a simple alternating-current system of transmission.

Recently, both in the United States and in England, the subject of underground systems, such as conduits or systems in which the line is divided into sections, current being switched on in succession, or by the passage of the car over the sections, has received a good deal of attention. A conduit has been successfully used in New York. The plough consists of a central web of insulating material carrying two contact pieces forced out against the conductors by springs. It has been a difficult problem to make this plough so that it is sufficiently durable. This plough seems to fairly meet the requirements. The cost of such a plough does not exceed £3. The maintenance in New York does not exceed 0·0005d. per car mile. Such a plough lasts six months, making 100 miles per day. The maximum speed is 17 miles an hour. The average high speed is about 12 miles an hour. The cost of this conduit is £17,000 per mile of single track. It has been stated that a conduit could be constructed that would be equally as good for less, but, in making this statement, the severe climatic conditions in New York had not been properly considered, and it is also to be borne in mind that former experience with conduits has indicated that, for anything like satisfactory results to be expected, the structure must be so laid that perfect alignment is maintained. Some similar conduits, but of less rigid mechanical structure, have been used in other American cities, but in no case is there encountered such severe climatic conditions as are to be met with in New York. The depreciation and maintenance of this particular conduit is less than any overhead system with which I am acquainted. The fact, however, remains that it is laid in a broad street, where there is perfect drainage and but little vehicular traffic across the rails, and that it is laid in a new part of the city, where troubles in laying from water pipes and gas pipes are largely avoided.

The sectional rail, and other systems in which there are switches at frequent points along the line so that a portion of it, less than the length of the car, is in circuit, are in an experimental stage. While I have seen some very successful models of such systems, the difference between a successful model and a perfectly working tramway appliance is so great that I shall not now discuss such underground systems.

I would call your attention to one of the details of the switchboard that has received great attention, and which has now attained to a very high degree of perfection, that is, the automatic circuit-breaker. I have seen a circuit-breaker open 6,000 amperes at 500 volts repeatedly, without burning the contacts, or making a serious flash. The circuit-breaker is reliable in its action, that is, it can be set to open for any desired current with accuracy. It has been frequently observed by tramway engineers of experience that there is a great difference in the quality of short circuits, that is, when these circuit-breakers are set for a given current the flashing is greater under some conditions than under others. This has sometimes been attributed to self-induction. The writer, however, does not hold this opinion; but a study of the switch will show that to maintain the necessary contact the weight of the moving part is appreciable, and it has, therefore, an appreciable time of movement. A short circuit may occur near the station, so that the current that would flow in the circuit, were it not interrupted, would be much greater than from a short circuit taking place in some other part of the system. This, together with the fact that the circuit breaker requires a certain appreciable time for operation would explain the different results observed.

In conclusion I would say that another of the minor improvements that has been carried out with this respect to the bonding of the rails. It has frequently been found that with the resistance between metallic surfaces brought together under pressure is greatly in excess per unit of area of that of the conductor. The improvements in jointing or bonding the rails together is to greatly increase the area of the pressure contacts so that the current density does not now exceed the capacity of the contacts. The writer's experience indicates that, with a permanent system of earth contacts, the current density should not exceed 50 amperes per square inch. In large systems, where the return circuits amount to several thousand amperes, the rails themselves are frequently welded together electrically. Such systems have been satisfactory in action, and mechanical difficulties that were anticipated in a solidly welded system of tracks, have rarely been experienced.

## THE ROYAL COMMISSION ON ELECTRICAL COMMUNICATION WITH LIGHTHOUSES AND LIGHT-VESSELS.

### FOURTH REPORT.

The following is an abstract of the Fourth Report of the Royal Commission appointed to inquire and report as to what lighthouses and light-vessels it is desirable to connect with the telegraphic system of the United Kingdom by electrical communication, for the purpose of giving information of vessels in distress, or casualties at sea, to places from which assistance could be sent, and of transmitting storm warnings.

In the last report, issued in April, 1895, the hope was expressed that, after visiting Denmark and inspecting the system of electrical communication with lighthouses and life-saving stations in that country, the Commission would be in a position to prepare the way for their final report. In consequence, however, of the serious difficulties which continue to be experienced in maintaining electrical communication with certain light-vessels on the system now employed, it has been decided to postpone the final report until attempts have been made by further experiments to overcome these difficulties.

*Connections which have been Effected.*

There are at present five light-vessels, six island, pile, or rock lighthouses, and 40 shore lighthouses around the coasts of the United Kingdom, which have been placed in electrical communication with the general telegraph system of the country at the national charge.

*The Danish System.*

In August last the Royal Commission visited Denmark and inspected the system of electrical communication with lighthouses and life-saving stations in that country. The system of electrical communication with lighthouses in Denmark is described at some length. Briefly, the system is practically an extension of the general telegraph system of the country. The use which is made of the wires for private and business purposes far exceeds the use to which the connections are put for the purpose of affording assistance to vessels in distress. Much of the important work which is done in the United Kingdom by the Coastguard, the Post Office, and various other agencies is carried on in Denmark by the lighthouse authorities. At Hanstholm, Hirshals, Skagen, and Hammeren lighthouses in Denmark, to which signal stations are attached, messages of any nature, made by means of the International Code of Signals, are received from passing ships, and are forwarded by wire to their destinations, and telegrams can also be sent to the lighthouses to be signalled to passing vessels. The masters of passing vessels make considerable use of the facilities which are offered to them for communicating with their owners and others. Any vessel making her number to one of the four lighthouses just named is reported by telegraph to the exchanges at Copenhagen and Aarhus free of charge, and the wires to the connected lighthouses are also used for sending reports of the state of the weather and the ice to various quarters. The multiplicity of duties which the staff at some of the principal Danish lighthouses have to perform does not appear to affect the efficiency or popularity of the lighthouse service, in which appointments are eagerly sought after. One male and one female assistant, the latter often a member of the family of the head keeper, seem, with help when necessary from the rest of the staff, to be equal to the work of attending to the signal station and telegraphing all the various messages which have to be despatched, as well as of receiving those which are forwarded to the lighthouse. The Government give to the head keepers at those lighthouses at which there are signal stations and telegraph offices special allowances, out of which they have to provide for the proper performance of the duties of those branches of their work. The arrangement gives the head keeper a more direct personal interest in the work of signalling and telegraphing than he would have if special assistants were appointed and paid by the Government for the purpose: it prevents the incurrence of the additional pension charges which would be thrown upon the State if the work was done by assistants belonging to the lighthouse service, and it has worked well and satisfactorily for all parties concerned. The Royal Commission was unable to ascertain what has been the cost to the State of establishing electrical communication with lighthouses in Denmark, or what the annual expenses and receipts are, but the latter, they understand, are not sufficient to counterbalance the expenses. This is no doubt due in part to the fact that the Danish

Digitized by Google

Government allow the wires to be used free of charge for such purposes as reporting passing vessels to the exchanges, and sending notice to different quarters regarding the presence of shoals of fish. Messages sent by private individuals have, of course, to be paid for, but the Danish Government seem to regard the electrical communication on the coasts of the kingdom as having been established in the interests of the maritime community, and make no charge for the use of the wires when the messages sent are for the general advantage of that community or any section of it.

*Working of the Electric Cables to the Light-Vessels and Outlying Lighthouses which have been connected.*

As the record of failures of the cables during the twelve months ended December 31, 1895, is one of considerable technical interest we print it in full.

"Kentish Knock" light-vessel.—(1) On May 18, 1895, the veering (electric) cable, which had been laid on November 21, 1894, was found to be broken on the ground. As the light-vessel then on the station was about to be replaced by another vessel, the repairs were not effected until June 11th, when the new vessel was moored in position. (2) On July 12, 1895, communication was interrupted, the veering (electric) cable having been broken by the lightship riding to it. Communication was restored on July 16th. (3) On December 7, 1895, the veering (electric) cable parted, the sheathing having become damaged some time previously. The necessary repairs were effected on December 9th, and no further interruption in communication occurred during the year.

"Goodwin" (North Sand Head) light-vessel.—(1) On January 30, 1895, the veering (electric) cable, which had been laid on September 15, 1894, was reported to be broken, the cause of the rupture being the general decay of the sheathing below the patent swivel. Owing to the cable ship being engaged elsewhere repairs could not be effected until April 10th. (2) The cable laid on April 10th lasted until October 24, 1895, when it broke, owing probably to the parting of one of the arms of the chain cable by which the light-vessel was moored. Bad weather delayed the repair of the vessel's moorings, and electrical communication could not be restored until November 22nd. No further interruption occurred during the year.

"Hasborough" light-vessel.—(1) On May 18, 1895, the first cable to the lightship, which had been laid on October 2, 1894, parted below the patent swivel, owing probably to its having been nipped by one of the lower shackles of the swivel. Communication was restored on June 5th. (2) On November 19, 1895, the veering (electric) cable broke. Owing to bad weather, communication was not re-established until December 1st. (3) Communication was again interrupted on December 8th, and was restored four days later. No further interruption occurred during the year.

"Shipwash" light-vessel.—The first cable to the lightship, which was laid on November 17, 1894, lasted without repair until August 20, 1895, a period of 276 days, when it parted. As the cable ship was engaged on other work, the necessary repairs were not effected until a month later. No further interruption in communication occurred during the year, but as the result of a heavy gale, the outer sheathing of the veering (electric) cable was damaged, and some repairs were effected on December 2nd.

"Formby" light-vessel.—Electrical communication with this lightship in Liverpool Bay was established on October 20, 1895. The cable, which is about four miles in length, places the light-vessel in telephonic communication with Crosby lighthouse, which is in electrical communication with Liverpool and the neighbouring lifeboat stations. This vessel has been supplied with a new form of veering (electric) cable of a more flexible nature, and protected with rings of lignum vitæ, in order to save it from being chafed by the mooring chains, and by the light-vessel herself. No interruption in communication had occurred up to December 31, 1895.

"Gunfleet" pile lighthouse.—No interruption in electrical communication had occurred since the cable was laid in October, 1893.

"Tuskar" lighthouse.—Telephonic communication with this lighthouse had not been interrupted since it was established on September 10, 1894, although the cable was slightly injured in October last.

"Fastnet" lighthouse.—In our first report we recommended the establishment of electrical communication with this lighthouse, which is situated about seven miles off the south-west corner of Ireland. The precipitous rock on which the lighthouse is built is exposed to the full force of the Atlantic seas, and is unapproachable except in calm weather. In 1885 electrical communication by a continuous cable was established with the lighthouse at the instance of the Committee of Lloyds, who had received permission to use it as a signal station, but the difficulty and expense of maintaining the connection were so great that it was abandoned at the end of 18 months, after several lengthy interruptions in communication had occurred. Having regard to the difficulty of maintaining electrical communication with the Fastnet by means of a continuous cable, it was recommended that a non-continuous system should be tried, and effect was given to the recommendation on July 18, 1895.

The system employed in this case deserves some explanation, as it has been found to provide a satisfactory means of electrical communication under very unfavourable circumstances. A submarine cable of the ordinary type, 7·0283 knots in length, is laid from a small bay, called Galley Cove, towards the lighthouse; the sea end is spliced to 17 fathoms of heavy copper wire, insulated with india-rubber and protected by lignum vitæ rings, and this wire terminates in a copper mushroom anchor weighing 4½cwt., which is submerged in 11 fathoms (low water) at a distance of about 60ft. from the Fastnet. The shore end is connected by a subterranean cable with the Post Office at Crookhaven from which is laid another cable 200yds. long, terminating in a copper centipede anchor, sunk in about two fathoms of water in the haven on the further or north-east side of the promontory on which the post office stands. At the Fastnet two short copper conductors, connected with the instrument in the lighthouse, are bolted on to the sides of the rock, one on the north, or land side, and one on the south side, each terminating under water in a copper centipede anchor. This is the present arrangement, but one of the conductors having been broken by the action of the sea, it is proposed to protect the exposed parts of both conductors by passing them through holes which will be drilled in the rock for the purpose. The mushroom anchor near the rock, and the centipede anchor in the haven, form the earth-plates of the line—the post office at Crookhaven, with its batteries and instrument, being intermediate. The circuit is completed by the sea, but part of the current passing through the circuit is picked up by the nearest copper conductor on the rock, and actuates the telegraph instrument placed in the lighthouse. It then passes through the other copper conductor into the sea. In the reverse direction part of the current sent from the lighthouse is picked up by the mushroom anchor, and passing along the main cable, actuates the telegraph instrument in the post office at Crookhaven. The instruments used, both at the lighthouse and at the post office, are a double-current speaking key and a dead beat d'Arsonval reflecting galvanometer, and the signals are those of the Morse Code. Except for a short period, when one of the conductors on the rock was broken, telegraphic communication has been maintained throughout the winter; but it has not been possible to apply the ordinary arrangement for calling attention by means of a bell, and it has, therefore, been necessary for the operators to go to the instruments at stated intervals to ascertain whether there was anything to communicate. Now that the winter has passed, and it has again become possible to work on the rock, no time will be lost in fitting a call-bell, which will be worked by a specially-devised relay.

"Caldy Island" lighthouse.—This lighthouse, in Carmarthen Bay, was electrically connected on July 29, 1895, and no interruption in communication occurred during the year.

"Maplin" pile lighthouse.—Electrical communication was effected with this lighthouse, off the north entrance to the Thames, on September 5, 1895, and no interruption had occurred up to the close of the year.

*Concluding Remarks.*

It will be seen that, as far as the lighthouses are concerned, the cables which have been laid have worked satisfactorily. The first outlying lighthouse which was connected with the mainland was the Gunfleet pile lighthouse, which was placed in electrical communication with Walton-on-the-Naze on October 2, 1893. Since that date four more outlying lighthouses (excluding that on Lundy Island) have been connected, and, although some of these stations are in very exposed positions, communication has not been interrupted with any one of them except the Fastnet.

As regards the cables to the light-vessels the returns are not so satisfactory as was anticipated, but there is reason to believe that many, if not all, of the interruptions have been due to remediable causes, and endeavours are being directed to removing those causes and also to experimenting upon a system of communication by induction as suggested in the last report. Under this system the cable running from the shore is laid in a circle on the bottom of the sea immediately under the light-vessel, the circle having such an area that the vessel will always be within the circumference of it. Round the deck of the light-vessel a number of turns of insulated wire are coiled, which are in connection with a telephonic receiver on board the ship. An intermittent vibratory current is sent through the cable, and is made and interrupted by a Morse key. The vibrations act by induction on the coils of wire on the light-vessel and produce buzzing sounds in the telephone, which, being intermitted by the Morse key, are read as in the ordinary Morse code. By means of a special arrangement a call-bell can be rung. In the same way messages can be sent from the light-vessel to the shore. This system has not yet been subjected to a practical test at a lightship; but the Commission regard it as offering greater chances of success than any of the other inventions of the same nature which they have had before them, and meanwhile defer recommending the establishment of electrical communication with any further light stations, awaiting the result of the experiments which are about to be made.

The Report is signed:—

Mount Edgcumbe (Chairman), Dunleath, Edward Birkbeck, F. L. McClintock, G. S. Nares, J. C. Lamb, W. H. Preece, John A. Kempe, R. Munro-Ferguson.

## MEETINGS OF SCIENTIFIC SOCIETIES, &c.

**(To-day) FRIDAY, June 5th.**

Royal Institution.

*9 p.m.* Evening Discourse: "Electric and Magnetic Research at Low Temperatures," by Prof. J. A. Fleming.

**WEDNESDAY, June 10th.**

Municipal Electrical Association.

*10.15 a.m.* First Annual Convention at the Royal United Service Institution. Presidential Address by Mr. Arthur Wright: "The Municipal Electrical Association and its Objects." Four Papers to be read and discussed.

*4 p.m.* Visit of Inspection to the London Electric Supply Corporation's Works at Deptford.

Institution of Electrical Engineers.

*7.30 p.m.* Students' Visit to the Bankside Central Station of the City of London Electric Lighting Company.

Royal Society.

*9 p.m.* Annual Conversazione at Burlington House.

**THURSDAY, June 11th.**

Municipal Electrical Association.

*10.15 a.m.* First Annual Convention at the Royal United Service Institution. Four Papers to be read and discussed.

*5 p.m.* Visit of Inspection to the Islington Electricity Works, Elen Grove.

## ELECTRICAL BOOKS AND PUBLICATIONS.

*All Books, Newspapers, and other publications can be ordered direct of* 'THE ELECTRICIAN' *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

**ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced).** Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

**ELECTROMAGNETIC THEORY.** By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

**THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE.** By Dr. J. A. FLEMING.

**VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS.** NEW EDITION. Price 12s. 6d., post free.

**VOL. II.—THE UTILISATION OF INDUCED CURRENTS.** Price 12s. 6d., post free.

**ELECTRIC LAMPS AND ELECTRIC LIGHTING.** By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

**MAGNETIC INDUCTION IN IRON AND OTHER METALS.** By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

**ELECTRIC MOTIVE POWER.** By A. T. SNELL. 10s. 6d.

**THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical).** By Dr. GEORGE GORE. Price 10s. 6d., post free

**ELECTRO-CHEMISTRY.** By Dr. GEORGE GORE. Price 2s., post free.

**PRACTICAL NOTES FOR ELECTRICAL STUDENTS.** By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free

**DRUM ARMATURES AND COMMUTATORS (Theory and Practice).** By F. M. WEYMOUTH. Price 7s. 6d., post free.

**THE INCANDESCENT LAMP AND ITS MANUFACTURE.** By GILBERT S. RAM. Price 7s. 6d., post free 8s.

**A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ.** By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

**"THE ELECTRICIAN" PRIMERS.** In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

**THE WORK OF HERTZ.** By Dr. O. J. LODGE. Price 2s. 6d.

**A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c** By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

**THE MANUFACTURE OF ELECTRIC LIGHT CARBONS.** A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

**THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS.** Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

**SUBMARINE CABLE LAYING AND REPAIRING.** By H. D. WILKINSON. [*Nearly ready.*

**MOTIVE POWER AND GEARING.** By E. TREMLETT CARTER. [*In preparation.*

## STEEL-PLATE PORTRAITS

*Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz: Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field: Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; Dr. Heinrich Hertz; Mr. R. E. B. Crompton; William Sturgeon; and Dr. John Hopkinson, F.R.S., have been issued as Supplements to* "THE ELECTRICIAN."

*Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.)*

## LOW-FALL WATER POWER.

It is high time that engineers and persons interested in engineering enterprise should cease to talk of water power as a specially free gift of Nature, and to enlarge on the theme of the many millions of horse-power running to waste that might be utilised at no expense. That the subject lends itself to poetical treatment is undeniable, and undeniable also is the ease with which such poetic utterances may be used to decoy capital into unprofitable paths. There is a sense, of course, in which it is true that water power is freely bestowed upon this earth by Nature, but it is the sense only in which it is also true that every good thing is the gift of a providential arrangement of the universe. The water power which we use, or which, if we chose, we might use, for driving machinery is not more freely bestowed than the coal which we dig, or which, if we chose, we might dig, from the bowels of the earth; or than the oil which we pump, if we wish, from oil wells; or than the natural gas, which we can pipe line from vent holes to our furnaces and gas engines. Every good gift and every perfect gift of Nature is providentially so bestowed that it cannot be used without the expenditure of both capital and labour.

Our attention has been directed to the utilisation of water power, and especially of low-fall water power, in this country, by a Paper which has recently been read by Mr. ALPH. STEIGER before the Institution of Electrical Engineers. Quite rightly the author of that Paper states that low falls are more frequently met with in this country than high falls; indeed, speaking of England alone, and not of the whole of Great Britain, we have no really high falls, and scarcely any of even moderate height. England is the land of gentle, unbroken streams rather than of waterfalls and cataracts. It is important to notice this in any estimate of the value of the water

Digitized by Google

power of the country from an electrical engineering point of view. For the cost of developing and working a water mill varies enormously with the available fall, being much greater with low than with high falls. In the very first sentence in his Paper Mr. STEIGER strikes the true keynote—the cheap production of electrical energy. But, having struck the right keynote, he proceeds to play the whole tune in a wrong key. In no single instance, among the many examples he has cited, does he even touch upon the question of cost, either as to the initial cost of the works necessary to develop the mill site or as to the annual expenditure involved in up-keep and attendance. To make matters still worse, he chooses examples which mostly are as free from the conditions of low-fall water power utilisation as it would be possible to find. We are treated to purely descriptive accounts, and interesting but far from convincing pictures, of such works as those at the Falls of Foyers, where the fall is 350ft., and of several installations on the Continent, with falls of 170ft. and under. At most of these places the machinery has been erected by Messrs. ESCHER, WYSS and Co., for whom the author of the Paper is, we believe, the British agent. The only characteristically English water-power plant described is that at Brantham Mills, where the falls varied from 4ft. 10in. down to zero. Here again, however, we find nothing but the most meagre information as to the results which have been obtained. We can admire the ingenuity with which the turbines have been designed to give a nearly constant speed on a widely-varying fall, and we concur in the author's opinion that such a result can only be obtained when there has been careful adaptation in the design and construction of the turbine and outworks to the local conditions, all of which, be it noted, costs money. But we look in vain for any data upon which we might base an estimate of what it would be likely to have cost, if, instead of erecting a flour mill at Brantham Mills, an electric supply station had been erected. The question as to whether or no any given low-fall mill site should be utilised for the production of electrical energy is not: Can the resources of engineering design and skill be made to combat the vagaries of a given mill site to such an extent that reasonably large and fairly constant power can be obtained? Nowadays the ingenuity of engineers can accomplish anything. But the question which ought to be asked, before deciding to commence operations, is: When everything that can be done here has been done to make this a successful mill, what will it all have cost, what will it cost to keep going, and would it have cost more or less if instead of developing this mill site we had gone to the most convenient spot and erected a steam station? It is this latter question which Mr. STEIGER's Paper in no way assists engineers to face. Yet, until we have faced it, how can we ever hope "to show how water power under low falls can be, and is, very advantageously and economically utilised for the generation of electrical energy"?

Occasionally one finds the argument advanced—and Mr. STEIGER's Paper is not free from it—that because electric supply stations worked on moderate and low falls have proved to be successful in Switzerland and in other countries, therefore success may be expected with them in this country. The argument neglects several important differences between the conditions of the countries compared. In the majority of English localities coal is very cheap, and nowhere in this country is it so dear as in Switzerland or in India. Here, too, other sources of power, such as coal-gas, producer-gas and petroleum are much more readily and cheaply utilised than they could be in many foreign countries where water-power plants are to be found. Here, also, land and labour are dearer, and as a result it costs more to construct the works necessary for the continuous usage of a mill-site where the flow is intermittent. Nor should we forget that in a level country like England one of the greatest inconveniences arises from an excess of flow, which "tails-up" the tail race—*i.e.*, floods it to such an extent that there is practically, sometimes absolutely, no fall; while, however large or small the flow may be in the comparatively few low-fall mill sites in Switzerland, the water will always be able to get away clear of the tail race without ponding back. And the marked liability of a water-power station to become crippled, together with the Englishman's dislike to fall back on tallow candles when the electric light fails, render it necessary in this country that all such stations should be provided with auxiliary plant, driven by steam or some other reliable source of power. This increases the prime cost by a considerable amount; and, moreover, even if the stand-by plant is never used—an ideal case, alas, purely supposititious—it is necessary to spend something every year to keep it in order.

These considerations are no doubt trite and obvious, and some will wonder why we have been at so much pains to show that there is small prospect of success in the utilisation of low-fall mill sites in this country. No one, we may be told, expects to see a crop of water-power stations spring up in England. But it must not be forgotten that capital has already been spent on this sort of enterprise, a notable instance of which is furnished by the Worcester-Powick water-power station. The experience of the owners of that station might not indeed have been more fortunate had the water-power side of the system never been adopted, and any attempt to blame the water power exposes the critic to the retort that things would have been better had it not been for the day load at the pumping station. Be that as it may, we venture to think that the Worcester authorities are not now quite so proud of their steam-and-water-power station as they were at the start; and it would not surprise us to see the whole of the water-power department abandoned and the station run entirely by steam. In fact, entailing as it does the transmission of power and the freight of coal by road each over a distance of three miles, the present situation of the generating station is inconvenient both for obtaining fuel and as a centre of supply; and in the event of such a transformation, it would probably suit Worcester better to have its generating station nearer the town. In any case the experience of Worcester furnishes an object lesson, which it would be well for anyone in this country who contemplates a similar utilisation of low-fall water power to learn by heart.

## REVIEWS.

**An Elementary Treatise on the Calculus, for Engineering Students.** By JOHN GRAHAM, B.A., B.E. (London: E. and F. N. Spon. 1896.)

An elementary knowledge of the differential and integral calculi cannot but be regarded as a most valuable adjunct to the mental training of the engineering student. It is not a necessary part of his education in the same sense that a working acquaintance with the slide-rule is, and in the exercise of his profession he may seldom have occasion—even if he have the ability—to apply it to any new problem, of which the solution cannot be found in some standard work. It remains, therefore, somewhat of a luxury reserved for those who aspire to the higher branches: and to all but a few of these, its chief use lies in the fact that it throws open so many of the best books on physical and engineering science. Yet if once acquired, the student will seldom regret the hours that he has spent upon it, and no time is so suitable for its acquisition as that which is passed at the technical college. If he does not then master the

Digitized by Google

main principles on which the calculus is based and attain some facility in applying it to simple cases, there is but little likelihood of his doing so when once he has become immersed in the routine of the office, the workshop, or the central station.

The avowed object of the present book is to impart just such an elementary knowledge of the calculus, and it is admirably adapted for its purpose. It forms one of the Finsbury Technical Manuals, and we may trace in it the influence of Prof. Perry's lectures to the Finsbury students. The general order and arrangement of the purely mathematical portion must needs be much the same as in the standard mathematical text books; but the difficult question of how much must be inserted and how much may be omitted without making the treatment cumbrous or incomplete, has been satisfactorily decided by Mr. Graham. Many of the illustrations and examples in the first 200 pages are borrowed from engineering subjects, and serve to enliven the usually dreary pages of mathematical formulæ. The fifty pages of the remaining two chapters are devoted entirely to problems of mechanical and electrical engineering, and of these we can only complain that they are too short. Even at the expense of making the book larger, we think that the engineering examples might with advantage be multiplied, and if in especial we wish for more electrical problems, our demand must be ascribed to our natural bias in favour of electricity.

The ordinary student unconsciously absorbs a certain knowledge of the calculus through the graphic methods, which are now so commonly employed, and nothing renders the subject so clear as appropriate curves. But the great difficulty of the inquiring mind is to fully acquiesce in the differential calculus as a truly logical process. We hardly think that this difficulty is sufficiently faced and overcome. Why should one small quantity, A, be neglected when some other small quantity, B, is not neglected? Granted that quantity A is considerably smaller than quantity B, is the neglect logical? Some books tacitly convey the impression that A may be neglected "for practical purposes." But surely this is a most erroneous statement of the case, which cannot be too strongly combated. The differential calculus has no affinity to the practical art of knowing "what to leave out." The answer given in our author's first chapter is no doubt correct, but is it sufficiently radical? It must rest on the logical concept of the limit of a function, by reason of which the process is absolutely true. Hence we should have liked to have seen more about "limits," so as to compel the assent of the reader.

After this initial mental difficulty, purely mathematical processes carry the learner forwards. Maximum and minimum values of functions find suitable illustrations in Lord Kelvin's rule for the economical sections of electrical conductors and arrangements of cells in a battery, and the application of the calculus to plane curves ends the differential portion.

The processes of integration are then discussed, and followed by their chief applications to the areas of plane curves, of surfaces of revolution, and to volumes of solids of revolution, &c. Fourier's theorem is next treated, and the periodic functions of various curves are developed, the chapter ending with an example for the student which might well represent the flat-topped curve of E.M.F. of an alternator. Possibly room might have been found for a more physical discussion from the point of view of harmonic motions, which are not mentioned. Finally, the most important forms of differential equations are explained and illustrated.

The whole book thus forms a suitable introduction to such a work as Prof. Unwin's "Elements of Machine Design"; or, again, to Prof. Fleming's "Alternate Current Transformer," in which the calculus often appears, and always in so lucid a manner that the student may follow the reasoning. Inspired by success, may he then find time and energy to cope with the more recondite examples to be found in Mr. Oliver Heaviside's writings!

We trust that the second edition of Mr. Graham's book will lead to the disappearance of the table of errata which now confronts the reader as he opens on page 1; and that this second edition may quickly be reached will be the wish of everyone interested in the training of electrical engineers.

**Contrôle des Installations Électriques au Point de Vue de la Sécurité.** By A. Mommerqué. (Paris: Baudry et Cie.)

This book, which has the support of the Minister for Commerce (Posts and Telegraphs) and the Minister for Public Works and Railways, will doubtless find a large field of usefulness, although necessarily limited by obvious considerations to France. It is one of the first, if not the first, attempt to summarise the various public regulations controlling the distribution of electric power in different countries, and also to give in a compendious form the results of experience as regards the best methods of carrying out electric undertakings with due regard to economy of production and to the security of the public.

The first four chapters discuss the practical side of the subject, and give a summary of fundamental facts and methods most in vogue for producing and distributing electric power by continuous and alternate currents. The next deals effectively with the risks and difficulties besetting electric distribution, and the best manner of controlling them. Both danger to life and damage to water and gas pipes are considered very fully. The four chapters following treat of the methods of controlling power station, network, house-wiring and tramways, and contain much practical knowledge in a crisp form. In the concluding chapters the various regulations in force in France are examined in detail. These are interesting, but of course have no special application for engineers here, who find sufficient trouble of their own in our various municipal and Board of Trade regulations.

Among the codes of rules we note those of the British Board of Trade, dated up to June, 1894. This date does not bring them up to date, as it omits the important concessions made February 6, 1896, in which low pressure is defined as not exceeding 500 volts.

The book is well written, and the mathematics, which are of a practical character, are admirably clear. It should prove of much use to French engineers engaged in the supply and distribution of electric power.

**Les Applications Mécaniques de L'Energie Électrique.** By J. Laffargue. (Paris: J. Fritsch.)

This is a handy reference book, giving in a popular way a rough summary of the applications of electric power for factories, mines, aboard ship, agricultural purposes, &c., in Europe and America. There is no serious attempt to describe in detail any of the numerous plants instanced, and hence the usefulness of the book is limited. It is intended to be used in conjunction with a previous work by the same author, in which the practical and theoretical sides of the subject are discussed in detail, and in this connection it possesses undoubted value. Standing alone, the book seems to partake rather of the catalogue order, and might be fitly published by any of the large continental firms for the use of its customers. The last chapter contains a number of tables referring to the advantages of electric power in comparison with steam, compressed air, ropes, belts and hydraulic power, with costs of installations, efficiencies and annual charges. This part will be found both interesting to the consumer of power and to the constructing engineer. The author does not claim that the figures are all absolutely correct, but he considers them to be fair averages, as they are compiled from recent data.

The illustrations of all the sections are mainly from photos, and, although of no artistic merit, are valuable as being true copies of the originals.

Written primarily for use in France, the book is likely to prove interesting to anyone using or about to use electric power who has the necessary elementary knowledge of the French language.

---

**The British Association.**—The Mayor of Bristol, following a suggestion of a deputation representing local scientific institutions, has decided to invite the British Association to visit Bristol in 1898. Should this arrangement become a fixture, as well as that for Dover in 1899, the British Association will be "booked" up to the end of the present century.

# THE UTILISATION OF WATER-POWER, ESPECIALLY WITH A SMALL FALL, WITH SOME EXAMPLES OF PLANTS FOR THE GENERATION OF ELECTRICAL ENERGY.*

BY ALPH. STEIGER.

*(Concluded from page 158.)*

The description of a Jonval turbine installation which I supplied for the Brantham Mills, near Manningtree, in Essex, here illustrated, will show that a very small and varying fall can be utilised with great advantage to obtain nearly a constant power. The local conditions and requirements are most remarkable and interesting. The power is used to drive a modern flour mill, in which the maintenance of a regular speed is of equally great importance as for driving an electrical plant.

The river Stour is a tidal river, with a maximum fall at ebb tide of 4ft. 10in., while at high tide the fall is *nil*. The water is supplied partly by the river itself coming down from the hills of Cambridgeshire, and partly by the rising tide filling the river bed above the mill for a considerable length. The power required is 40 actual horse-power, and it was stipulated that this power should be maintained down to a fall of 40in. On starting the turbine, it was shown, however, that it drove the mill at full capacity and at

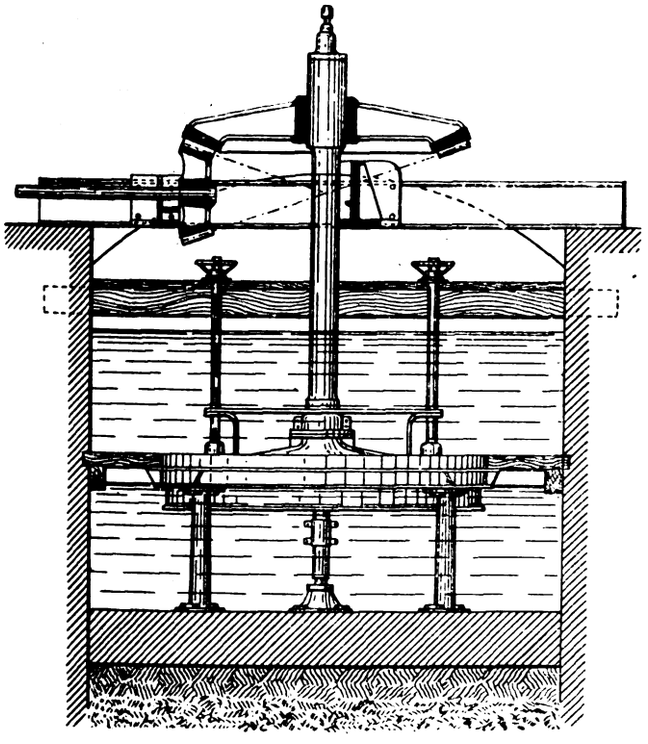

FIG. 5A.—Turbine at Brantham Mills, Essex. Cross Section.

full speed under a fall reduced to 32in. The full power is available during 16 hours of each day, while during six further hours the power corresponding to a fall reduced down to about 1ft. is still utilised for driving a part of the machinery. Comparing the useful power obtained from this varying fall by the new turbine during 24 hours with that obtained by the undershot water-wheel previously working, it is nearly six times larger.

The turbine consists of only two concentric rows of buckets; the inner one is provided with gates, which are opened or closed by hand-wheels, an automatic governor not being generally used in flour mills. The outer row of buckets is just large enough to give the full power required under the maximum fall. As the fall is decreasing by the rising tide, the gates of the inner row of buckets are gradually opened to make up the power by an increased quantity of water, and the more water is passing through the buckets of the inner row the more it acts on a reduced mean diameter, thus maintaining also the proper speed without perceptible loss of efficiency.† The power is transmitted from the turbine on to a horizontal main shaft by means of a pair of bevel wheels. This horizontal shaft is made to run at 75 revolutions, and is provided with a clutch by means of which the turbine is connected with the steam engine if the mill is required to work continuously. When the fall is reduced to more than 32in., the mill is, however, driven separately by the steam engine, and the power of the turbine is used to drive the wheat-cleaning machinery, and eventually some pairs of millstones which can work independent of the automatic roller mill plant. When the fall is reduced to 15in., the power that is still obtained from this turbine is 7 H.P., the turbine naturally running slower; but still this power is quite sufficient to be profitably utilised.

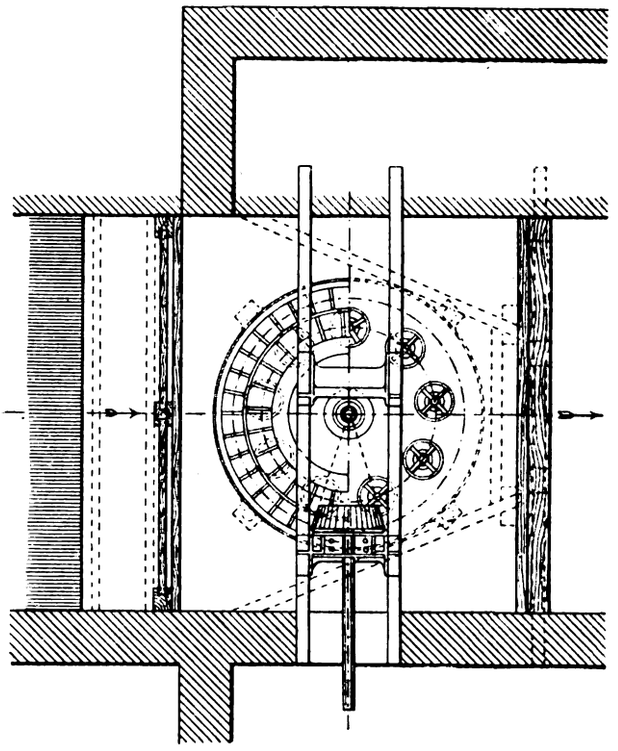

FIG. 5B.—Turbine at Brantham Mills, Essex. Ground Plan.

Assuming that the water power available at Brantham Mills were applied for the generation of electric energy, it would, in the first instance, be necessary to obtain a conveniently high speed to drive an electrical generator without much intermediate gearing. A turbine similar to the one actually working could be made for

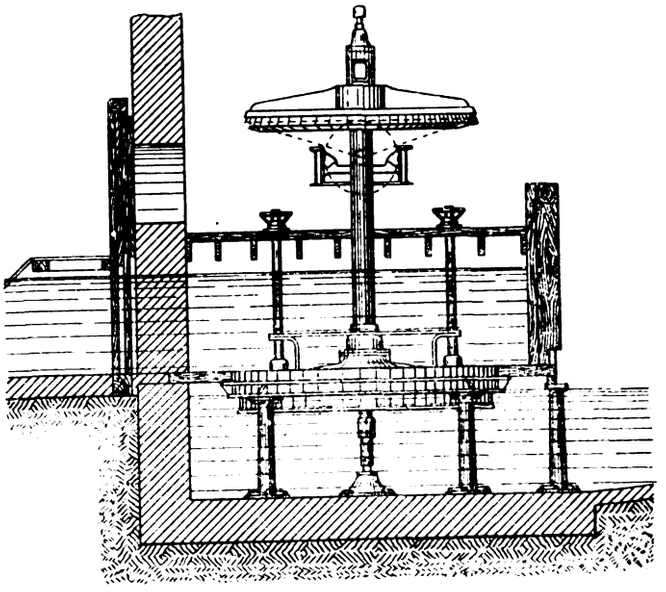

FIG. 5C.—Turbine at Brantham Mills, Essex. Longitudinal Section.

exactly these conditions, running at 30 revolutions per minute, and a pair of bevel wheels put in of such proportions as to give the first motion shaft a speed of 150 revolutions per minute This speed would be very suitable to drive a dynamo of 40 H.P. by means of a belt or ropes. A higher speed of the turbine than 30

* Paper read before the Institution of Electrical Engineers.

† The outside diameter of this turbine is about 10ft., and it runs with 24 revolutions per minute

Digitized by Google

revolutions would, for such a low fall, only be obtainable at the expense of efficiency. As in this special case the fall, and consequently the power, varies with the rise and fall of the tide, the full power of the turbine can, of course, only be relied on during 15 or 16 hours every day. The power produced during the time when the fall is diminished beyond the limit at which it is 40 H.P., and at less than the normal speed, could probably be applied to charge electrical accumulators.

The construction of the turbine shaft deserves some notice. The space underneath the turbine being always filled with water, and, therefore, inaccessible, the pan for the footstep is placed on top of a column round which the hollow cast-iron shaft revolves. The upper part of the turbine shaft is widened, and contains an adjustable steel pin which revolves in the pan or cup, filled with oil. Although a well-constructed footstep will last for years without requiring repairs, an easy access to it is of great advantage.

Similar turbines were erected by me in other mills near Norwich, Reading, and Lewes. In all cases the fall varies between (23 inches) 2ft. 6in. and 6ft., the reduction of the fall being caused by floods, while the water supply varies in the proportion of about 1 to 4. In each case the local conditions were carefully investigated and the turbine constructed accordingly. The good results obtained in each case are due to the careful *adaptation* of the turbine to the conditions. The importance of a careful consideration of local conditions is evidenced by several failures which were recently brought under my notice. In one of these instances, the turbine—which in itself is a very good motor—gives very poor results, owing to the disregard of the actual conditions of the locality. Even the construction of some details of a turbine depends sometimes on these conditions; and in several cases now under consideration I have had to depart from the general practice of designs of turbines, in order to secure the highest results when most required.

How varied the construction of a Jonval tube may be, will be shown by the following examples. The turbines of the Geneva Waterworks, built by Messrs. Escher, Wyss and Co., of Zurich, work under a maximum fall of 12ft. during the winter season, when the water supply is shortest, while during the summer season the water supply stored up in the mountains, in the shape of snow and ice, is abundant. The large summer supply reduces the fall, however, to 5ft. 7in. The power of each turbine, of which there are now 17 at work, is 210 actual H.P., and they run at a uniform speed of 36 revolutions per minute, whether the fall is 5ft. 7in. or 12ft. The cost in this case was a secondary question; the turbines have, therefore, been provided with the best possible arrangements to suit the large variations of the fall and quantity of water. The drawing shows three concentric rows of buckets. The outer row alone will develop 210 H.P. under the maximum fall of 12ft.—its outside diameter is 14ft. Each of the two inner rows of buckets is provided with a revolving gate, working separately. Each turbine drives a pair of double-acting plunger pumps direct, the crank common to both pumps being fixed on the vertical turbine shaft.

An interesting turbine installation, under a fall varying from 10ft. 9in. to 8ft. 10in., in connection with electrical generators, is that at Baden, in Switzerland. It was described in *Engineering* of November 1, 1895. This plant was erected to supply the town of Baden with electric light, and the necessary driving power to the new works of Messrs. Brown, Boveri and Co., the well-known electrical engineering firm. The fall had to be created by a weir, and a canal about 2,500ft. long, which added considerably to the cost of the plant. Each of the three turbines is of the Jonval type, giving off 200 B.H.P. It is impossible to build a turbine of that power for the fall available in this case, which would run with a speed high enough to drive a generator direct. The turbines run at 40 revolutions per minute, which speed is maintained under the varying fall by means of gates for the inner row of buckets. The generators—two-phase dynamos of the horizontal type, made by Messrs. Brown, Boveri and Co.—run at 200 revolutions per minute, and are driven direct off the turbine shaft by means of a pair of bevel wheels. The exciter dynamos, of which there are three of 10 H.P. each, are driven each by a separate turbine. These small-power turbines naturally run at a higher speed—namely, 180 revolutions per minute—and drive, therefore, the exciter dynamos without any intermediate gearing.

In most cases in this country where a good water supply is available, the fall will be rather lower than 10ft. or 12ft.; it will therefore require intermediate gearing to drive a high-power generator, and it will even not often be possible to connect it direct with the first main shaft driven off the turbine by bevel wheels. Belt drives are very convenient to get up the necessary speed of dynamos, but for large power they are very expensive, and absorb a considerable amount of the power in friction. The ordinary round hemp and cotton rope is objectionable, on account of requiring frequent repairs and re-splicing. During an inspecting tour in Switzerland last summer, I came across a new kind of hemp rope, which seems to supply just what is wanted to drive large-power dynamos. A piece of this patent rope is here for inspection. It is a plaited rope of extreme pliability, which does not stretch. I found this rope working at the generating station of Schaffhausen. The power at the generating station is transmitted from the countershafts, driven off two turbines of 300 H.P. each by means of bevel wheels, on to the generators by means of 10 such ropes, $1\frac{3}{4}$in. thick. The rope pulleys on the dynamos have a diameter of 5ft., running 300 revolutions per minute. The rope pulleys on the countershaft have a diameter of 13ft. 6in., and the distance between the centres of shafts is 51ft. The power is electrically transmitted to a spinning mill about half a mile distant from the generating station. The secondary station consists of an electromotor of 200 H.P., coupled directly to a main line shaft,

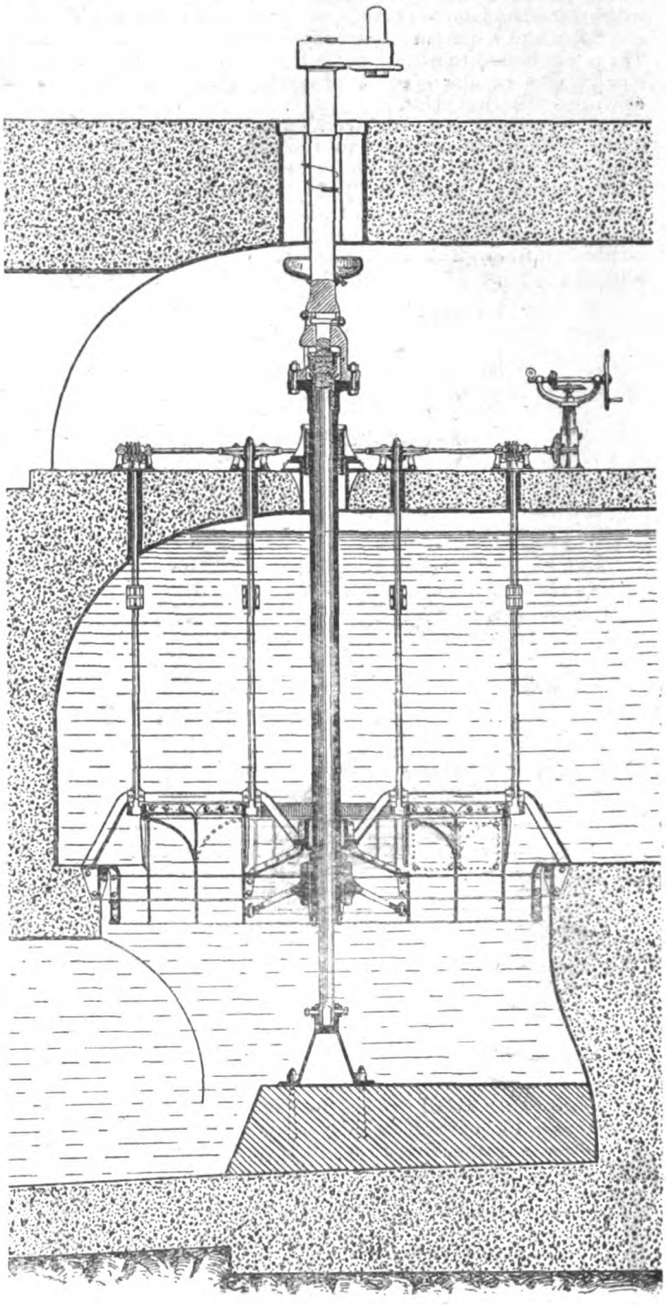

FIG. 6.—Turbines of the Waterworks, Geneva.

and two electromotors of 190 H.P. each, coupled together. The latter, running at 300 revolutions per minute, carry a rope pulley of 5ft. diameter with 14 grooves. 100 H.P. are transmitted by four such ropes to a shaft 21ft. above the electro-motor, at an angle of 51deg., while the remaining 250 H.P. are transmitted to another shaft on about the same level and 17ft. 8in. distant, running with 130 revolutions per minute. In spite of the unfavourable relative position of the shafts these ropes work with extreme regularity and easiness, and their adaptation has, according to the manager of the spinning mill, put an end to the trouble and frequent stoppages caused by the breaking of the round ropes which were previously used.

Returning to the description of water-power plants proper, two more examples in connection with the generation of electricity deserve to be mentioned, showing how certain objects can be attained by a special construction. One of these is the installation of five new turbines for the aluminium works at Neuhausen, on the Rhine fall, in Switzerland. One of these turbines is here illustrated. Each of these turbines gives off 610 B.H.P. under a fall of 66ft., with a quantity of water of 6,500 cubic ft. per minute. With the high fall a high speed suitable for driving the dynamo direct is naturally obtained—an arrangement which has also been adopted in this case to economise space. On the other hand, the load on the footstep of a turbine of the power mentioned by the pressure of the water, in addition to the weight of the armature of a generator of corresponding dimensions, is so great that a special arrangement had to be adopted to release the footstep of at least a part of that load. In order to overcome this difficulty, the turbine has been reversed, the water passing through the turbine upwards, acting, therefore, in the opposite direction to the weight of the machinery. The boss of the turbine wheel is, moreover, formed into a piston, working in a cylinder, to which water under the pressure corresponding to the fall is admitted, thus counteracting again the weight of the moving parts of the turbine and dynamo. The water, after passing through the turbine, is conducted to the tail-race through a suction tube, the turbine being placed 15ft. 9in. above the tail water. It runs at 150 revolutions per minute, and is a single Jonval turbine. To regulate its speed, if required, a ring gate is inserted in the suction tube, while it can be stopped by a throttle valve in the wrought-iron tube taking the water to the turbine. The total power now utilised by these aluminium works is 4,550 H.P. The turbines were constructed by Messrs. Escher, Wyss and Co., of Zurich, and the dynamos by the well-known electrical works at Oerlikon. Each dynamo is of 7,500 amperes and 55 volts.

The last turbine installation here illustrated is that at Zufikon-Bremgarten, also in Switzerland. The drawing shows another arrangement to counteract the weight carried by the footstep, and at the same time an arrangement by means of which the necessary speed to drive a dynamo of large power direct under a medium fall is obtained. The plant consists of four sets of double Jonval turbines of 325 B.H.P. each, running at 115 revolutions per minute, and a smaller Jonval turbine of 34 B.H.P., driving two exciter dynamos, running with 210 revolutions per minute, and was erected to supply electric light to the neighbouring town of Wohlen, and driving power to the new works of Messrs. Escher, Wyss and Co. in Zurich, and a large flour mill close by these works. The distance over which this power is transmitted is about 11 miles. The fall is 17ft. 6in., and was obtained by building a dam across the river Reuss, and a tunnel about 1,100ft. long across a hill round which the river flows at a rather high speed. The water is divided between two Jonval turbines fixed on one common shaft, so that it passes upwards through the lower wheel and downwards through the upper wheel. By distributing the water in this manner, the diameter of each turbine is reduced, and the speed consequently increased. At the same time the pressure of the water, which would otherwise act on the footstep, is entirely counterbalanced. The central part of the lower wheel is, moreover, formed into a disc, on which the water presses from below, releasing the footstep also partly by the weight of the revolving parts of the turbine and the dynamo. The space between the two turbines on each shaft is connected with the tail-race by a flume formed of concrete, which acts as a suction tube. This turbine

Digitized by Google

plant was also erected by Messrs. Escher, Wyss and Co., and the dynamos were built by the Oerlikon works.

The examples given above of the utilisation of water power may be considered as representative types of successful installations under different conditions. They are sufficient in number and variety to prove the necessity of a selection from motors which are different in principle, and of the careful adaptation of the turbine selected to the local conditions and requirements.

A turbine installation under a low fall will be more costly than one under a higher fall; it is, consequently, of special importance to obtain the highest possible efficiency, even at an extra expense, under a low fall. The cost of the turbine itself is only a fraction of the total outlay for the plant, including foundations, connection with the machinery to be driven, and sometimes a weir and a canal. The cost of these permanent structures exceeds that of the motor; it is, therefore, a penny wise and pound foolish policy, after putting in the permanent structure, to try and cut expenses by putting in a turbine of insufficient capacity or inferior efficiency. The commercial value of a water power depends rather more on the annual outlay on the same than on the first cost, and the annual outlay for the work obtained from the power is the smaller the higher the efficiency of the plant.

The efficiency of a turbine which can be obtained and honestly guaranteed, even if the fall is low, is about 75 per cent. Eighty per cent. and a little over is sometimes obtained under favourable conditions, and has been proved by careful tests made by responsible experts; but an efficiency of 85 and 90 per cent., sometimes claimed, is never reached, if the quantity of water be *accurately* measured during the test. If the efficiency of the turbine is guaranteed at all, it should be stated not only for the most favourable conditions, but also for a reasonable *minimum* of the fall or the quantity of water.

In many instances within my own knowledge, water power, in itself sufficient to drive the machinery of a factory, but improperly utilised, is supplemented by artificial power, produced by steam, gas, or oil engines. The loss of money caused by the waste of the cheap power from a running stream in this manner amounts certainly to a big sum in this country alone. The annual cost of such auxiliary power, calculated for 3,000 working hours, may be put at three to four times the cost of water power, and calculated for 6,000 working hours, four to eight times the cost of water power. A judicious utilisation of the water power in such cases would not only result in an enormous saving of money, but in a gain of a large amount of power now unutilised. Most factories are closed at night time, when the water is allowed to run away without being made use of. Assuming that the water power is insufficient to drive all the machinery in the daytime, while it is wasted during the night, electrical storage batteries in connection with a generator might very advantageously, and perhaps with greater economy, be used instead of auxiliary steam, gas, or oil engines.

It seems probable that in the near future the electrical transmission of power will take the place of shafting and belt drives in factories, when certainly the waste of water power would be prevented in the manner suggested. Owners of factories driven by water power might even find that by improving their water power they obtain spare power which could be profitably applied by the generation and distribution of electrical energy in the immediate neighbourhood. I may add that the majority of large-power central stations now being erected in Switzerland for the generation and distribution of electrical energy are mostly utilising small or medium falls varying between 10 to 30 feet. The storage of water in the shape of snow and ice on our mountains provides us with a good water supply during the summer, but the low temperature in winter reduces that water supply very considerably. The water power there is just as variable as in other countries, and those falls which can be advantageously utilised on account of being situated in the inhabited and industrial districts are often not any higher, or not much higher, than in this country; the only difference being that such small falls occur more frequently, rendering a concentration of large power in one place easier, and perhaps less costly. Still, it is my conviction that concentration of water power for the distribution of electrical energy, or for the generation of a large amount of electric current, as required for electro-chemical and electro-metallurgical processes, is possible in many places in this country without going into prohibitive expenditure for canals, &c.

In conclusion, I hope to have succeeded in my endeavour to show how water power under low falls can be, and is, very advantageously and economically utilised for the generation of electrical energy; and that a very large amount of water power is now running to waste which could, in conjunction with electrical machinery and apparatus, be turned to profitable account by such a hearty co-operation of the electrical and the water-power engineer as has resulted in such success of commercial enterprise in my native country.

## DISCUSSION.

*Mr. TREMLETT CARTER said that he wished that a more competent person than himself might open the debate; but there were a few remarks he wished to make relative to the utilisation of low falls for electrical purposes, especially such falls in this country. Mr. Steiger had promised, in the opening part of his Paper, to prove the utility of low falls, and at the end of it he said he hoped he had succeeded in his endeavour to show that low falls can be economically used for electrical generation. Mr. Carter trusted he might be pardoned if he failed to appreciate Mr. Steiger's logic. The author had given a number of examples of water-power utilisation. He had first given the Falls of Foyers, where the fall was 350ft.; next he mentioned Chaux-de-fonds, where the fall had been stated to be "only 170ft." Brantham Mills were described with a fall of 4ft. 10in.—quite a low fall—but that case was a flour mill. The turbines made only 24 revolutions per minute—quite an impossible speed for a dynamo, without considerable loss of power in the gearing that would have to be used. Then Mr. Steiger mentioned the Geneva Waterworks, with a minimum fall of 5ft. 7in., which was also a non-electrical example; after which he gave the case of Baden, a 10ft. 9in. fall. That was an electrical example, but the author furnished no particulars as to the results obtained or the cost of the scheme initially. The author next cited the Neuhausen aluminium works, electrical enough, but the fall is 66ft. Then came the description of the Zutikon-Bremgarten installation, with a fall of 17ft. 6in. Mr. Carter thought that the figures given in these examples did not go to prove that low falls were useful for electrical purposes in this country.

Mr. Steiger had stated that England is a land of low falls, and Mr. Carter agreed with him there; but low falls were subject to several distressing complaints. In the first place, there is the complaint of too little water, owing to drought. But that was nothing to the complaint of too much water. He had seen what might be described as a very desirable mill-site laid under a vast sheet of water—mill-race, tail-race, almost the whole mill, under one level extent of flood, and that, not because of any unusual catastrophe, but merely because there had been a little extra heavy rain. This was a very common thing in the low falls of this country, the tail-race being frequently "tailed up" or ponded back to such an extent that the turbines will not work. Another very distressing complaint occurs in winter, when the mill-pond, mill-race, turbines, in fact everything, get frozen up. There was still another common complaint from which low-fall mill-sites in this country suffered. He referred to the principle of "first come, first served," that obtained in a great many of the English rivers and streams. He would give an example to illustrate this. A small electric supply station with which he was familiar was driven by undershot water-wheels, with secondary batteries and a steam engine as stand-by plant. It was quite a complicated affair. The principal trouble at this station arose on account of the action of a miller, whose mill is situated a short distance up the stream. A miller is nothing unless thrifty, and before that miller leaves his mill in the evening he shuts down the main sluice, and saves up the whole river for the morning. Now, the electric light station wants the river mostly during the night, but cannot get it. It can only get it in the daytime. You cannot work a water-power station when someone has switched off the river, or if you wish to run the station during the night you must dig a mill pond large enough to store up half a day's worth of river, so as to be able to get water when the miller next door higher up has shut down. At the station mentioned Mr. Carter said it was impossible, for special reasons, to have a big mill pond, so they had to put in a large secondary battery plant, and everyone would realise how inefficient it would be to depend to so large an extent on batteries. Those were some of the difficulties and troubles which were encountered on low falls, and all these troubles made it absolutely necessary to put in steam or some other stand-by plant, which enormously added to the initial cost of the undertaking. Stand-by plant will in fact duplicate the horse-power of the generating machinery, though, since steam plant is cheaper than low-fall water-power plant, it does not quite duplicate the cost.

But even if we had a low fall from which these vices were absent, Mr. Carter pointed out that there would always be this objectionable feature—that an enormous mass of water would have to be dealt with, per unit of power, as compared with a high-fall plant. He would give an example which would show this to be the case. Suppose we wanted to get 1 kilowatt at the switchboard; then, with a low fall of only 3ft., and allowing an over-all efficiency of 50 per cent. between the turbines and the switchboard it would require a flow of 3,000 gallons per minute. He thought Mr. Steiger would agree that 50 per cent. was a very liberal allowance for the efficiency, taking into account the fact that double or treble reduction gear, belts, &c., would have to be used. He had seen mills where the power was taken a sort of personally conducted tour over the mill, before being ultimately taken to the dynamo. Now compare the 3,000 gallons per minute with what would be necessary on a fall of 350ft., such as at the Falls of Foyers. The efficiency might easily be 70 per cent., and in that case only 18 gallons per minute would be required for 1 kilowatt at the switchboard. The larger bulk of water in the low-fall plant would entail far more expensive works and engines, to give sufficient water-way. Besides this, so much water in motion was a difficult thing to control, and would increase the trouble in governing. It was difficult to get very close governing with any type of water plant; but on a *low* fall the difficulty was enormous, owing to the huge mass of water to be controlled quickly. Mr. Carter also took exception to Mr. Steiger's advocacy of impulse turbines for dynamos on moderately high falls. To select these, as had been done at Foyers, in order to suit them to the speed of the dynamos, was wrong, and it was altogether a new thing for dynamos to require the engine to be built to run as slowly as possible. The turbines ought to be adapted to the mill-site, and then the dynamos adapted in design so as to run direct-coupled to the turbines.

Looking at the comparative costs of low-fall water power and coal or other sources of power, Mr. Carter thought that low falls were not cheap. Mr. Steiger had referred to water power as "a free gift of Nature," but he (Mr. Carter) thought there was often a legacy duty of 100 per cent. Nothing was to be made out of it. It was better to use coal, which we paid for, than to have to depend on a free gift like this, which came only in wet weather.

*Mr. ALEXANDER SIEMENS, in thanking Mr. Steiger for bringing his Paper before the Institution, said that it was very interesting to learn what had really been done in Switzerland, even if the falls of the various installations could not exactly be called low falls. He thought the Paper quite proved that low falls were adaptable for driving steadily, as in the case of the Manningtree Mills. But in saying that he said all that the author had really been able to demonstrate in favour of low falls. He had said that the mills were run about 16 hours a day. They had two interruptions of four hours—a tidal interruption—and therefore some addition to the "free gift of Nature" had to be provided. With regard to the objections brought forward by Mr. Carter, he might mention that they were founded on experience. The author had brought forward his Paper with a view to teaching them that water-power was applicable to electric driving; but it should not be forgotten that Lord Armstrong, nearly 20 years ago, put up at his private house a small installation with water power to light his picture gallery, and at the same time had a motor driving a lathe or saw or something of that kind. The original installation he believed was even at work at the present day. Further, in 1881 the town of Godalming was lighted by low-water power. There was a mill, with all the advantages described by Mr. Carter, which was utilised for driving the dynamos; and Godalming certainly had the distinction that it was the first town in the whole world to have all its streets lighted by electricity, and lights distributed to private houses where required. Unfortunately, however, very little was required, and the thing was not a financial success—it was before its time. Fifteen years ago there were mills working under exactly the same conditions mentioned by Mr. Carter; and those were the drawbacks in England of utilising water power. It could not be relied upon; it could not be worked by itself. They must have something to fall back upon; and when they had to put up steam plant, or whatever it was, capable of dealing with the whole of the lighting, why complicate the matter by having water-power plant alongside! He was sure English engineers were quite awake to the beauty of water power, where water power was attainable; but the low falls in England were, as far as he could judge, not adapted to electric lighting.

Mr. SHOOLBRED asked to be permitted to mention a long-standing example of a low fall not mentioned by the author—the celebrated Menier's chocolate works in France. That fall was a peculiarly difficult one, varying from about 5ft. 6in. to as low as 15in. at times. The whole of the River Marne was there dealt with. One interesting feature connected with the falls there was that Girard's impulse turbines were used, which the author had stated were difficult to manage with low falls. Those turbines had been working there for a very long time. There were three of them, and they adapted themselves admirably to the differences of falls. Recently, however, as Dr. S. P. Thompson had told the meeting, the largest of these, that for the smallest fall, had been replaced by an ordinary undershot wheel. He thought that sometimes impulse turbines were of use generally; but he quite admitted that under certain circumstances reaction turbines, especially with low falls, might be found to be more useful on the whole. Impulse turbines, however, should not be altogether set on one side. Most of the author's examples were confined to the Jonval turbine. There was a reaction inward flow turbine which had been used for many years in this country, and which from its authorship ought to be highly acceptable to electrical engineers. It was known as the "Thomson reaction inward flow turbine," the inventor being the late Prof. J. Thomson, brother of Lord Kelvin. In illustrating the low falls in Switzerland and the value of water power in that country, the author had forgotten the fact that the circumstances under which the water supply was obtainable there were directly opposed to what they were in this country. He referred more particularly to the time of year. Mr. Steiger had stated that it was in summer especially that they obtained their largest supply of water. The greatest difficulty experienced in this country when dealing with low falls was the absence of water, and in some instances, as Mr. Carter had mentioned, floods occurring at a certain time of the year. It was the absence of water, in summer especially, that rendered it difficult to utilise hydraulic power with advantage, as engineers in this country otherwise certainly would. They were bound ultimately to fall back upon steam power, and then came the question, Why complicate the matter and add to the capital outlay by having two sets of plant, one of which was lying idle for half the year?

*Mr. M. MOWAT said he quite agreed with the author that there was a great deal of motive power running to waste which might be utilised with very great advantage in the interests of the country. He believed the time would gradually come when water power would be far more utilised than it was at present. He had had no experience as an expert in the preparation of the necessary plant; but his firm, Messrs. Ritchie, Steuart and Co., of Bombay, as representing the Gokak Water Power and Manufacturing Co., were perhaps at the present time employing a larger amount of water power than any in Her Majesty's dominions. About 13 years ago his firm secured a lease from the Government of India of the power at the Falls of Gokak in the Southern Mahratta country. They had now eight turbines of 250 H.P. each. They were using 1,500 of that horse-power, soon they would be using 2,000 H.P., and they intended ultimately to work up to something like 4,000 H.P. Mr. Steiger had mentioned what had been done as to turbines and plant employed, but he had given no commercial results which are essential. Some of those results he could himself supply. He was glad to be able to say that Messrs. Escher, Wyss and Co., for whom Mr. Steiger acted as agent, had supplied his firm with the plant. The water fall was 200ft. high. The capital employed there in two mills was £200,000, and the plant to utilise that water power cost about £22,000. By the utilisation of water power instead of coal they were able to give a larger dividend than they could if they used fuel. The work done at the mill was of the best character. He might mention that his firm was not one of those who allowed water to run to waste during the night. They took care of and husbanded every available cubic foot, so as to have it for work during the day. The driving was not done by means of dynamos. The two mills were at a distance of about an eighth of a mile from the turbines, and by means of large wire ropes, supplied by a firm in Newcastle, the mill was driven. The plant had worked splendidly, no hitch having ever occurred. He mentioned that as showing what water power could do. The utilisation of power, as mentioned by Mr. Steiger, could not fail to do a great deal of good. The more the question of water power was looked into and the power availed of, the greater would be the benefit to a great industrial country like ours.

*Mr. STEIGER, in reply, said that Mr. Carter had stated that impulse turbines were only suitable for extremely high falls, and that even in the case like that at the factory at Foyers they were unsuitable. He most emphatically contradicted that statement. The actual plant at this factory differs slightly from the diagrams. An impulse turbine, or "action" turbine, was suitable anywhere for a fall of 3ft. up to any number of thousands of feet, where it was constant and could be regulated according to the quantity of water without loss of efficiency. If a miller shut off the water at night and prevented his neighbour a little lower down working his electric plant, that was not the fault of the power but the fault of the laws which permitted such a state of things. In every country where water power was appreciated the law made very strong restrictions preventing anybody from having the right to take away water from his neighbour during the time he did not use it. [Mr. Carter said that he had carefully gone into the legal point of the question, and found that they were not blessed with such a law as that in this country.] Mr. Steiger said that water power would be much more appreciated in this country when it was really known what could be done in that direction. With regard to the automatic governors, alluded to by Mr. Carter, he might mention that they worked on low-fall turbines as well as on high-fall turbines; and on the latter the connection of an automatic governor to obtain exactly the proper speed was just as difficult as in the former, because under a high fall the areas through which the water giving a large amount of power passed was so small that by a trifling movement a very great variation of power could be produced. The application of an automatic governor for a high-fall turbine was sometimes an extremely difficult question, but it could be done by properly studying the conditions and proper means. With regard to the adaptation of turbines to dynamos, or dynamos to turbines, it had been found convenient in the case of the dynamos used in the aluminium works at Neuhausen, and in other cases where large dynamos were used, to connect them direct with the turbine shaft. If a dynamo required a diameter of, say, 10ft. such as the dynamos at Lyons, then the speed of the dynamo was given and the turbine maker would supply a turbine which would suit that speed.

Mr. Siemens had alluded to the failure of the turbine plant at Godalming for the electric lighting of the town. He did not know what sort of turbine was used, but certainly it had been proved, in more instances than those which he had given, that a water-fall varying from 1ft. to 5ft. or 6ft. could be used, and the power obtained was satisfactory. If the fall and quantity of water corresponded to a power of say 100 H.P. for nine months of the year, it was useless to put up a dynamo and plant requiring 150 H.P. Those conditions must be gone into before putting down a plant. A turbine even of the highest efficiency for any fall or quantity of water cannot give power beyond that which is in the water, just as a dynamo would probably not give more than 95 per cent. or so of the power for which it was constructed. Mr. Shoolbred had alluded to action turbines on low falls, but he had overlooked the fact that it had been mentioned in the Paper that low falls were very seldom found without variations of the water levels. That was a great difference. If he had water power, where the tail water never rose, or where the difference was only a few inches, then he certainly applied an action turbine; but in the case of driving dynamos, where he wanted to use as high a speed as possible, he would give preference to a reaction turbine, not on account of the inferiority of the action turbine under such conditions, but on account of the higher speed desired, which he could only obtain from the reaction turbine. He could make a reaction turbine smaller in diameter for a good fall than an action turbine, because a reaction turbine was less sensitive to the variations of the angles at the inner and outer circumference of the buckets. Mr. Mowat had alluded to a plant in India. That plant was under rather a high fall. The turbines are similar to those at Chauxdefonds. They were impulse turbines, and had, he thought, given satisfaction to the owners. Mr. Shoolbred had alluded also to the water wheel of Prof. Thomson. He had seen that wheel once, but not the actual plant. He believed it was a turbine which gave a good efficiency at full gate. He could not say how the efficiency was at part gate. It was a pity that so few tests had been made in this country with turbines so as to give reliable information as to their value. Anyone requiring a turbine should insist on having a written guarantee that it must give a certain power on such and such a fall, with such and such a quantity of water, and also under worse conditions on which the turbine might work for a considerable length of time.

*Gen. WEBBER, in moving a vote of thanks to Mr. Steiger for his Paper, reminded the members that whatever the criticism might be as to the use of water power in the past, and whatever the opinions, such as those expressed by Mr. Carter, might be, this was a very large and important question, and they ought to be very thankful to a gentleman of the experience of Mr. Steiger for coming forward and giving them a Paper which he regarded, and which he thought the meeting would regard, as an

Digitized by Google

inducement to many to go more deeply into the question. He was in the habit of inspecting water powers of that character, water powers with low fall and great irregularity, and he was sure that none of them could fail to call to mind instances in which it would be well worth their while to go and investigate the circumstances, and see whether they could not utilise the power with which Nature had provided them at a very small cost.

*Prof. SILVANUS THOMPSON, in seconding the vote of thanks, said there was one little correction he should like to make to a remark made by one of the speakers. He had recently visited the mill of Menier and Co., where the fall of the river Marne was used, and he had found that on account of the diminution in the height of the fall at the time when floods were coming down the river they had been compelled to put in, in addition to the turbines, an undershot water wheel.

---

The following remarks have been communicated by Mr. GEIPEL: He had been anticipated in some of his remarks by Mr. Tremlett Carter, with whose views he generally agreed; but there were one or two points in this Paper not touched upon to which he desired to refer. Mr. Steiger recognised the difficulties in utilising low falls due to variations in head and quantity—in the one extreme you have all head and little water, while after heavy rain you may have abundance of water and little head, and between these two limits you have all degrees depending upon the proverbially variable British weather. Mr. Steiger proposed to meet these difficulties by subdividing the turbine into several compartments; it may be that in some cases this is a good arrangement, but Mr. Geipel had had some experience in the use of water power for electric lighting purposes, and found that the varying load on the dynamo adds again to the difficulties of the varying water power. It is also to be remembered that a turbine has a *critical speed* at which the best efficiency is obtained, and that this critical speed varies with the head of water, whereas, on the other hand, the dynamo requires one constant speed. He was of opinion that it is frequently preferable, therefore, to subdivide your water power and use several turbines, each driving its own dynamo. These turbines should be arranged for working at different heads, one should be for the maximum head, and of suitable size to use only the minimum quantity of water available under that condition. The second turbine should be suitable for a less head and larger quantity of water, the third more so, &c. The number of these units would, of course, be governed by the conditions. An additional advantage of this method is that repairs may be effected to one unit, whilst others maintain the supply. Mr. Geipel was quite aware that this system may not be economical in all cases, especially where the maximum available power is small; but in many cases it will prove, in his opinion, to give a very much better all round efficiency than the compound turbines referred to by Mr. Steiger.

There is a more important point only briefly referred to by the author, and that is the question of first cost, as to which the author writes "The commercial value of a water power depends more on the annual outlay than on the first cost." On this point, Mr. Geipel was directly at variance with the author. He had always thought that the annual outlay on turbines was almost negligible, and that the only other consideration was first cost; if that item be also negligible, why then the millennium of those gentlemen who regularly promote, as they do, in the public press, the utilisation of the tides, is verily at hand. It is, unfortunately, this very question of excessive first cost, which makes the power produced by low-water falls in tides so much more expensive than in the case of steam or other engines. The importance of first cost is being daily driven more closely home to the minds of all electric engineers, and for that reason it is to be regretted that this Paper contains no information whatever upon this important point.

The use of storage batteries for storing the power during periods when the power is not required is well known. Mr. Geipel has, in several cases, found it cheaper to construct a water reservoir, which, of course, effects the same purpose. With regard to the difficulty experienced by the author with round ropes, Mr. Geipel thought he must have got hold of a very bad quality of round rope. The arrangements of the pulleys are good, and the strain is only 80lb. to 83lb. per square inch, so that with good English-made round ropes we should have no hesitation in transmitting more than double the power with satisfactory results.

---

## ARC LIGHTING PRACTICE.*

BY ALEX. DOW.

Mr. John Hesketh's comments † on arc lighting practice in his country and this are both interesting and valuable. The paragraphs as to lamp supports, globes and carbons deserve the careful study of American electric light men, for it is in these particulars that our practice has been, and still is, susceptible of much improvement.

In the matter of carbons it is not so very long since American 10-ampere lamps, whether for indoor or outdoor use, were uniformly fitted with $\frac{7}{32}$in. or $\frac{1}{4}$in. carbons, moulded solid and copper-coated. Sometimes the lower carbon was not coppered; when the lamp was used for interior lighting this was considered preferable, but neither the use of cored uppers nor of an upper of greater diameter than the lower was admissible. The practice to-day is much better. The introduction of arcs on constant potential systems brought in the imported carbons, with cores of differing diameters; and the alternating arc was a rank failure until a proper carbon and a 30 or 33 volt adjustment were adopted.

The $\frac{1}{4}$in. coppered carbon still holds the field in street lighting, and is likely to hold it for some time to come. The practice of using partly burned uppers in the lower holders, and double carbon lamps for all-night street lighting, are the factors of greatest importance in deciding this, because they require the purchase of but one size of carbon (usually 12in. long, but $\frac{1}{4}$in. diameter) and yet allow of every piece of carbon being fairly burned out, the short lengths produced at one season being mated and reissued to the trimmers at another. The worst fault of the $\frac{1}{4}$in. uniform carbon plan is the tendency to and "lapping" of points during the run—that is to say, the dropping of the upper carbon past the point of the lower, causing a short arc or total extinction. If the current is a trifle high, so that the conical points are longer than normal, or if the carbons are a little crooked, this trouble may become serious. Lamps on towers or other supports much affected by wind or vibration are specially liable to it.

In the plant I operate, analysis of the "outs" for two months showed that lapping was responsible for too much of the total trouble. We were running with $\frac{7}{32}$in. (11mm.) carbons in both holders, and a large number of lamps were on towers, while still another large number were on poles to which electric street railway span wires were attached. We changed to $\frac{5}{16}$in. (16mm.) uppers, retaining the $\frac{7}{32}$in. lowers. Result for four winter months' operation of 1,480 street arcs is just one "out" by lapping. We cannot see any practical difference in the total light. Experiments show a little difference, but it is negligible in comparison with the improved reliability.

When one turns from street lighting to interior work it is seen at once that the day of the uniform carbon is gone. I have only a dozen interior lamps—the incidents of a plant installed primarily for street work; but these dozen use three different carbons, to wit, 13mm. American-made cored uppers with 13mm, American solid lowers, forced, and not coppered, these being pairs for 45 volts by 9·6 amperes direct-current arcs, and 13mm. "Electra" cored, for alternating 30 volts by 15 amperes arcs. It is not unusual nowadays to find a station carrying in stock ten different carbons for interior work, and the use of uppers of larger diameter than the lowers is frequent, though not yet general. I fear that the refinements found in the best European carbon practice will (like the best of the European arc lamps) never acquire a permanent footing here. The effort to systematise which has reduced constant-current series arcs throughout the United States to two standard currents, 9·6 and 6·8 amperes, will reduce carbons to a very few sizes and styles. To our central-station men life is too short to fuss with lamps of the delicacy of chronometers and with carbons of different sizes for each month in the year.

I notice, however, the differentiation of the street-lighting lamp from that rented to private patrons. It is not long, say three years, since the total difference was in the style of the jacket—the street lamp jacket was japanned iron, while the private customer's lamp was done up in brass. Now the difference is radical. I have already noted it in carbons. In mechanism the private lamp (if I may so call it) is frequently a shunt wound lamp if run on a series circuit, and often it has a rack feed. The public lamp is usually differentially wound and almost always has a clutch feed. The difference in mechanism extends even to the adjustment of individual lamps, the station lampman cultivating a feed by imperceptible movements for the private lamp, which the said lampman calls a "sneak" feed, while on the public lamp he adjusts for a "drop" feed—that is to say, he tries to have the clutch kick itself entirely clear of the rod at the instant of feeding, causing a *drop* rather than a *slide* of the upper carbon, and the regulating magnet is relied on to immediately adjust the arc to the proper length when the clutch gets its new hold.

There is reason in all the differentiation. The shunt lamp (for the benefit of English readers I explain that a shunt lamp is that in which the separation of the carbons is produced by a spring or weight, while the magnetism due to a shunt winding draws them together; as distinguished from a differential lamp, in which the separation is due to a series coil)—the shunt lamp tends to regulate for constant volts at the arc without regard to the current. This is because the separating force of the spring or weight is constant. It follows that such a lamp will maintain a silent arc, if proper carbons are selected, with a very wide range of current. And so long as the average customer will insist on judging of his light by looking at the arc instead of at the illumination, this quality of the shunt lamp will much reduce the total of the "kicks" received per year. The sneak feed is, of course, the perfect feed and stops all hissing or flaming.

But consider the street lamp. It is differentially wound because with that winding a decrease of current shortens the arc and so reduces volts as well as amperes. For the normal condition of a dynamo on street-lighting work is full load, and its fre-

† "An English Engineer's Views on Arc Lighting Progress." By John Hesketh, A.M.I.C.E., M.I.E.E., Borough Electrical Engineer, Blackpool, England. *Electrical Engineering*, pp. 128-133, No. 38, Vol. VII. February, 1896.

Digitized by Google

quent condition is overload ; and it will be remembered that these series dynamos are designed with a drooping characteristic, an increase of current causing a fall of voltage, and the maximum voltage for any given speed corresponding to a current less than normal and to instability of point of commutation, so that a small further reduction of current will cause flashing. But with differential lamps in circuit, a reduction of current is at once compensated for by the shortening of the arcs, which reduces the necessary terminal voltage and assists in steadying the machine. It follows that such a dynamo can be operated with differential lamps nearer to its maximum voltage than with shunt lamps.

This gives the central station the equivalent of a reserve of dynamos for use in emergency. Of course, the light will be run with full current under normal conditions, and sufficient reserve for the common accidents of operation must be provided in the shape of spare dynamos. But it is possible, as we did experimentally not long ago, to operate 158 hissing arcs on a 100-light machine without putting any street in darkness, and much more to the satisfaction of the police and the general public than if 100 silent arcs had been maintained and the other 58 extinguished for the rest of the night. Had the lamps been shunt wound the limit would have been about 110, because each lamp would have insisted on getting full voltage for a silent arc, and that number would have put the dynamo on the top of its characteristic curve, and therefore to its flashing point.

As regards the drop feed, the reason is with the lamp. The lampman expects that lamp to stay in service and operate without cleaning or adjustment for at least a year, and if it stays out for two years he is not surprised. It has to stand summer heat when the running temperature of the mechanism is 150deg. to 160deg , and winter cold when the clutch and trips have to start work at 20deg. below zero of Fahrenheit scale. Also the rods have to be wiped many times by trimmers' cloths, which are not chemically clean ; and be handled by trimmers' fingers or mittens, as the season may decide, which said fingers and mittens are sure to be dirty. And that clutch is supposed to grip that rod every time and release it only on the call of the control magnet. Now the drop adjustment will, with a proper clutch, do its work whether the rod is clean or dirty, wet or dry, worn or new. It will feed a round file correctly, if the file is of the same diameter as the proper rod. You could not get a sliding feed with that file. The only fault of the drop feed is the momentary hiss, say two seconds, at the time of feed. On the street this is never noticed, though in interior work it would cause a claim for a rebate. And the compensation for this little fault is that the rod gets and needs no care but the daily wipe, and the adjustment needs attention only once a year.

But it is in outward appearance that the differentiation of the private and public lamp is most complete. The latter is still the same substantial, clumsy article, with no pretence to beauty of design or finish. The former is sometimes an artist's dream, and sometimes, alas, a nightmare.

Before quitting the subject of lamps, I venture to predict that the "inclosed arc," having the arc maintained in an inert atmosphere, will be the feature of private lighting for the present year. This is not a novelty, but it seems at last to have got past the experimental stage and to be a practical commercial article of decided value, particularly for interior work.

Mr. Hesketh's statement of his experience with a 60-light (3,000-volt) Ferranti rectifier is of much interest. As noted in my previous Paper, the rectifier has a province of usefulness, and the production of a successful 60-light machine enlarges that province, and also causes the hope that the device will soon be perfected in even larger sizes. It will, doubtless, be introduced in America before long, and our conditions will bring about the 100 and 125 light sizes. I do not see why, if a commutator on a dynamo shaft delivers 6,250 direct volts smoothly and successfully, a motor-driven commutator should not rectify a corresponding alternating voltage. The constant current transformer can be designed to give the same characteristic as the dynamo, and there is no vital difference between a rectifier and an "open coil ' commutator.

As to relative efficiency of the rectifier in Mr. Hesketh's station, compared with the 50-kilowatt direct dynamos here. He gets 73 per cent. I get identically the same. The efficiencies here are distributed as follows :—

Say of 1,000 watts indicated power in engine there are expended :

| | | | |
|---|---|---|---|
| 12½ | per cent. = 125 | watts | in engine friction, |
| 3 | „ = 26 | „ | rope transmission, |
| 14 | „ = 119 | „ | dynamo losses. |
| Total losses, 270 | | „ | leaving 73 per cent. net output. |

Data for these efficiencies were obtained from tests of the various parts. The engine friction is not unreasonably large in a triple vertical engine with 11½in., 18in., and 29in. cylinders ; 18in. stroke, and two 7,500lb. flywheels, at 200 revolutions per minute. Efficiency of rope transmission was obtained by comparison of pairs of dynamos direct-coupled, shaft to shaft, against the same pairs roped together, the one dynamo running as a motor and driving the other. The loss was almost the same at all loads and with different pairs, averaging 1,472 watts—a little less than 3 per cent. of 50 kilowatts. The dynamo efficiencies were got by several methods : By the Hopkinson method with three dynamos in series ; the same, but with a lamp load on the third dynamo ; by driving a dynamo by a previously calibrated constant-potential motor, *i.e.*, the motor efficiency was obtained by a brake test, and the efficiency so obtained applied to the power absorbed by it when driving the arc dynamo.

I do not question that the rectifier is more efficient than a 55-light Brush set. The dynamo in such a set has to contend with excessive engine losses, and is itself far from being an efficient machine. Its standing in the electrical community is based neither on its efficiency nor its good looks, but on its capacity for hard work and bad usage.

For the conditions of American practice in street lighting, the 100 or 120 light series circuit is a necessity. From where I sit tonight, in hearing of the "sing" of the brushes, the air line distance to lights in each of three directions is five miles, the distance by streets about seven miles. Many single circuits of No. 6 (0·162in. diameter) wire are 25 miles long. If those circuits were operated at 3,000 instead of 5,000 volts, the circuits would be greater not only in number, but in total mileage. The $C^2R$ losses on an output of 1,492 arcs and 25 "series" incandescents are nearly 65 kilowatts, say 8⅔ per cent. They will be about 7 per cent. on the increased output in prospect, as some of the longer circuits in the outer wards will be filled up with lamps. A return to 60-light circuits would mean an enormous increase in the copper, not only for new mains to divide the existing circuits, but for heavier copper to keep down the $C^2R$ loss to an economical figure. When an engineer has to plan a distribution for street lighting over 30 sq. miles of city, he is glad to use 5,000 or 6,000 volts for transmission, even at some sacrifice of station efficiency, and even when coal is but $2.25 (say, 9s.) per ton of 2,000lb.

As to engine efficiency—a larger engine would be a very little better. In my own case I sacrificed some net engine efficiency by insisting on the simplest possible valve gear, on outboard bearings, and on exceptionally heavy flywheels ; all of these points being to my mind essential to reliable operation. We use on test just 15lb. water per indicated horse-power per hour. In practice we don't do so well ; because, of course, there are more or less petty leaks of steam *out*, and of air *in* ; and because the auxiliaries (the independent condenser and feed pumps, and the little non-condensing set we run as an exciter for our "side-show" of incandescence lighting) are *not* economical. Practice shows 16·8 to 17·2lb. per horse-power per hour of the main engines. We put the heat of the steam from the auxiliaries back into the feed water, and it ends at the coal pile in the consumption of about 2·25lb. of coal per indicated horse-power. The most practical statement of all is that after we have run our trifling day load—some 35 to 50 H P.—and kept the steam pipes warm and the fire pump moving, and banked fires and done all the odd jobs of the 24 hours, we have used about 4·7lb. of coal per kilowatt hour of output. If we had a day load like the night load, we would get that figure down below 4lb.

I doubt whether a 500 H P. engine would be appreciably better in everyday practice, even with the refinements of Corliss gear or balanced valves. I see more possible improvement in properly proportioning the cylinder sizes to the average load than in the refinements of valve gear ; for there is nothing more common in American lighting practice than an underloaded Corliss engine, and nothing that can get away with more dollars without the suspicion of the operator. From the rather meagre data that reach me by the English technical papers, I suspect that the same trouble afflicts the English stations which use a few large units ; and that the superior economy of those equipped with a multitude of Willans engines of small size is due very largely to their never running an underloaded engine. The inherent economy of the Willans engine is a matter of proper cylinder sizes and of minimised temperature range ; and the practical economy is in a full load ; but you cannot get those ideas into a man who believes in valve gear. He will not believe you so long as the "clickety-click" of the trips sings a song of sixpenny saving in clearance and cut off, though there be a loop like a truelove knot in the card of the cylinder which operates as an annex to the Corliss gear.

But I don't object to trips in their proper place, nor to 500 H.P. engines, nor any other size of proper proportion. I selected my own size because I believed four dynamos as many as should be roped to one engine ; for the ratio of dynamo troubles requiring a stop of the machine is to engine troubles of similar importance nearly as one to four with such engines and such dynamos. Then I decided that the economical voltage of the system was 5,000 to 5,500, and assuming the standard current of 9·6 amperes for street lighting arcs, the set of four dynamos figured up to a little over 200 kilowatts. Cylinder sizes were selected to give equal steam economy at full load and at three-quarter load, because in a street lighting

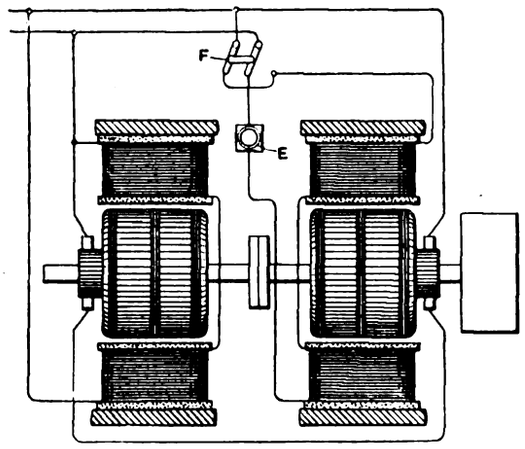
Digitized by Google

plant of four running sets it is always possible to divide the work so as to give each unit at least three-quarter load, and at any load between three-quarter and full the economy will be a trifle better. Shafts and bearings were made amply heavy enough for an overload, if an emergency should ever necessitate it, but one does not expect steam economy on an overload; it does not happen often enough to affect the annual economy, and if it be anticipated it is cheaper to meet it by increased steam pressure than by having the cylinders too large for normal conditions.

This disquisition has run away from arc lighting altogether, yet I trust it will be profitable to some arc lighting man who wonders where his coal goes to, seeing that both engine and boilers are plenty big enough to do their work and as much again. If that man will understand that his extra boiler capacity had better be standing idle, but ready to fire on a moment's notice, and that his big cylinders had better be traded for others of half the piston area to fit the same engine bed and shaft, he will have learned the first and greatest rule of central station economy.

## A METHOD OF REGULATING MOTORS.*

In the operation of electric motors from supply circuits, conditions are sometimes encountered in which a wide variation of speed is desired or essential. An example of this is a condition in which, for instance, it is required to deliver 10 H.P. at any speed between the limits of 100 and 500 revs, and to maintain this delivery at any desired speed between the limits above referred to. To accomplish this result, there have been two methods in use, one of which is to vary the speed by interposing resistance in the armature circuit, thereby reducing the voltage on the armature and consequently the speed. This method has the disadvantage that there is a comparatively large loss in the resistance, and consequently a low efficiency. The other method is to reduce the voltage upon the armature of the motor by introducing a rotary transformer between the supply circuit and the motor to be operated, which transformer



A System of Motor Regulation.

is so arranged that the voltage supplied to the motor may be varied between the limits of zero and a predetermined maximum. This method has the disadvantage of a large investment in dynamo machines, because the rotary transformer used consists of a primary motor and a secondary generator, each of which has an output equal to that of the main motor to be operated.

In the method about to be described, instead of using one motor, two machines are used, each of which will give one half the desired delivery. For instance, in the condition previously referred to, two motors of 5 H.P. each at 100 revs. are operated in unison, and cooperate with each other so as to fulfil the requirements of 10 H.P. delivery at any speed between the desired limits.

The accompanying illustration shows a diagrammatic embodiment of the method. The machines are coupled directly, E representing a rheostat, and F a reversing switch. The action in general is as follows: In starting and when operating at minimum speed, the two machines are acting in unison as motors. The speed is gradually increased until it reaches its predetermined maximum, first by reducing the field of one of the machines, thereby transferring the voltage of the line to the other, and then by reversing the field on the former machine and gradually increasing it, thereby adding to the line voltage the voltage of the former machine, the latter machine receiving the combined voltage. This method is due to Mr. James Burke, of New York.

# CORRESPONDENCE.

## ALTERNATING ARCS AND WAVE-FORMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I read with much interest in your issue of May 22, 1896, the letter from Mr. Steinmetz criticising your leader of May 1st. But I think that his historical sketch is more misleading than the absence of a sketch of which he complains, since he makes no reference to the first and more important works on the subject of the alternate-current arc curves.

The first indication of the distortion of a sinusoidal into a rectangular wave was given not by Messrs. Tobey and Walbridge in 1890, but by Prof. Joubert in 1881, and was taken as a basis for calculation by Dr. John Hopkinson in his celebrated Paper on "Alternate Currents" some years later. On the other hand, Mr. Steinmetz's Paper on the "Power Factor of the Arc," in *Elektrotechnische Zeitschrift*, in 1892, to which he refers in his letter, was anticipated by a Paper of my own presented half a year sooner, in April, 1892, to the French Physical Society, and abstracted about the same time in *La Lumière Electrique*. Lastly, the question of the distortion of waves by the alternate-current arc was for the first time fully analysed in another Paper published in *La Lumière Electrique* of September 16, 1893, that was abstracted for the Chicago Congress, and completed in *L'Industrie Electrique*, of August 10, 1895. This Paper covered far more than the actual subject under discussion, and contains one hundred curves of alternate-current arcs. Should Mr. Steinmetz and Mr. Frith favour me with a perusal of these curves, they would become better acquainted with the various conditions that can occur in the use of alternating arcs, and would fully recognise that their own conclusions are equally incomplete because they have not taken account of the nature of the carbons employed.

With the same alternator feeding an arc lamp one can produce P. D. curves of the most varied character, according to the material of the core, the length of the arc and the amount of the self-induction in the circuits (it matters little whether this self-induction be inside or outside of the alternator). With the low-voltage carbons actually employed in Europe in ninety per cent. of the lighting plants, the arc alters very little the form of the wave. To get the celebrated flat-topped form of wave it is necessary to employ high-voltage or coreless carbons, and in consequence *to put only two lamps in series instead of three* on 110-volt circuits. High-voltage carbons alter the form of the P.D. curve by making it flat-topped *even with low self-inductance machines*, contrarily to Mr. Steinmetz's opinions. The difference got by introducing high inductance is to make the ascent of the curve steeper, as I explained in my Paper, and all alternators may give the same curve with an alternate-current arc when the lamps are provided with sufficient inductance. Highly inductive alternators are very badly chosen if adopted for making studies of the arc, for it is impossible to obtain with them the various forms of wave attainable in the ordinary distribution at constant voltage where the inductance of the generating machinery is negligible in relation to that of the circuit. For this purpose, after experimenting with Gramme and De Meritens alternators, I myself soon came to prefer a machine of low inductance and sinusoidal E.M.F., in order to completely explain with it the effects of variable resistances and inductances, as well as the curious phenomena of the hissing arc that cannot be obtained with inductive circuits. Had but some attention been paid to these results, as I have paid attention to the works of English and American experimenters, probably many of the unnecessary questions on the subject could have been spared to those who have discussed it at the present time as one possessed of novelty.—Yours, &c., A. BLONDEL.

Paris, May 25, 1896.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Through your courtesy in forwarding me an advanced proof, I have read M. Blondel's letter on the subject of alternating arcs and wave forms. When M. Blondel wrote, my

Digitized by Google

Paper had not yet been published, and therefore he may be excused in assuming that I referred to the behaviour of the arc in altering the wave form as *possessed of novelty*. Further, M. Blondel would have seen that a reference was given to a former Paper from which the curves were taken, and which was translated in full in *L'Eclairage Electrique*, November 24, 1894, in which Paper the work of M. Blondel was specially called attention to. Indeed, I have always studied M. Blondel's work with much interest.—Yours, &c., JULIUS FRITH.

London, June 2, 1896.

## WAVE FORMS.—A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May we be allowed to point out an evident printer's error in your report of the Discussion at the Institution on May 14th? In the remarks of Dr. Fleming the following words occur:—

"*The authors seem to imply in their Paper that they had the idea at one time that the sine curve gave the greatest iron loss.*" We think that the word "they" should be replaced by the word "he" (Dr. Fleming), as the latter held the above (implied) opinion in his letter of June 28, 1895, in *The Electrician*.

The opinion we have expressed on all occasions is that the sine wave is a form not to be considered as *critical* with regard to the iron losses in transformers. The italics are ours.—Yours, &c.,

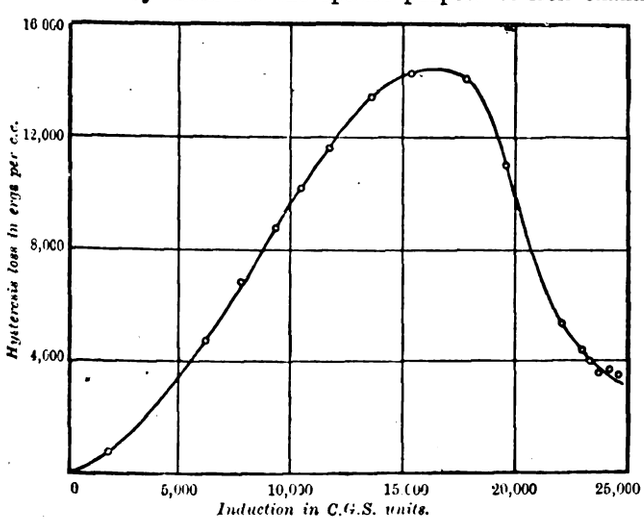
STANLEY BEETON,
C. PERCY TAYLOR,
JAMES MARK BARR.

## HYSTERESIS OF IRON IN A REVOLVING FIELD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In connection with the above subject, it may be of interest to your readers to mention that during the last six months experiments have been conducted in the electrical laboratory of University College by Messrs. R. Beattie and R. C. Clinker, by the aid of a revolving electromagnet constructed by them for the special purpose of iron examination. By the device of employing a very thin circular disc of iron or steel, suspended with its plane in a horizontal position, and hung on a torsion wire in the revolving magnetic field, they have been able to measure the relative values of the hysteresis in the iron for various inductions. The curve here given shows the results of some experiments, and it confirms Mr. Baily's discovery that beyond a certain value of the induction the hysteresis loss in iron in a revolving field is diminished. By the use of very thin discs of iron or steel the induction can be carried up to high values. The influence of any eddy current loss in affecting the deflection of the disc can be eliminated by experiments at various speeds of the magnet. The curve shows clearly that beyond a certain value of the induction the hysteresis loss falls off very rapidly. A fuller description of these experiments will be published at a later date by Messrs. Beattie and Clinker.—Yours, &c.,

J. A. FLEMING.



## ELECTRICAL TREVELYAN ROCKER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The "Electrical Trevelyan Rocker," described in your last issue by Mr. T. A. Vaughton as presenting "what appears to be a new electrical phenomenon," is a very convenient form of apparatus, but scarcely involves a novel principle. In the *Electrical Review*, Vol. XXVI., p. 656, 1890, there will be found a sketch of an electrical Trevelyan rocker, which depends upon this same curious effect. The phenomenon was observed in connection with some experiments upon electrically-driven tuning-forks, in which I required to leave the prongs free; *l. c.*, p. 57.

It may be interesting to Mr. Vaughton to know that if an ordinary Trevelyan rocker is balanced between its leaden block and a metallic knife-edge, and a current of, say, ten amperes is sent through it, the rocker will work without previous heating.

The "buzzing" in telephones is frequently due to a Trevelyan effect in the loose carbons of the transmitter; and it is not unlikely that the "hissing" of arcs may be associated with the same action.—Yours, &c.,

2nd June, 1896. ROLLO APPLEYARD.

## TRANSPARENCY OF FILAMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to the letter which appeared in your columns re the "transparency" of incandescent lamp filaments, I may point out that in my letter of April 16th I avoided the word "transparent" and used the phrase "transmitter of light."

I do not hold that my suggestion is the true explanation of the result obtained, as I gave the subject very little consideration: but I may point out that the fact of the filament casting a shadow of itself does not invalidate the suggestion I put forward; for does not a piece of opaque glass transmit light, and at the same time cast a shadow? while no one will say it is transparent in the everyday meaning of the word, *i.e.*, something you can see through.

Again, since the result we are discussing is a photograph, it is possible that the carbon at incandescence is a transmitter of actinic or chemical rays only. This would not in any way interfere with the shadow cast by the filament, but would still constitute the filament a transmitter of light.

It is quite possible that incandescent carbon may not be a transmitter of light at all, and the effect shown in the photograph be due to other causes; but at the same time the mere fact of the filament casting a shadow of itself does not negative the suggestion put forward originally, as I have shown above.—Yours, &c., ROBERT D. CASSELLS.

Pollokshields, N.B., May 18, 1896.

**Rope Gearing.**—A useful *brochure*, entitled "Manila Rope," has recently been issued by the C. W. Hunt Company of Rope-makers of New York, and forms a handy treatise on the use of ropes for the transmission of power. The early portions of the book describe the properties of manila fibre and the process of working it into finished cordage. These portions are usefully and interestingly illustrated, and among the pictures we notice an ancient Egyptian rope-walk. The illustrations showing splicing and fastening links are useful, though links have not much been used in this country. A number of tables and formulæ for rope transmission of power occur throughout the book, and a set of power curves enables the horse-power of any given rope to be determined for any given speed by simple inspection. From the sections of rope pulley grooves which are shown, it is evident that American practice differs from English in this respect. Doubtless this is partly or wholly caused by the tendency to run at higher velocities in America. Apparently the American grooves are easier and cheaper to cut, but we doubt if they wear out the rope so slowly as in English practice. However, this is merely our impression on examining the sections shown. Certainly, in some plants in America cotton and manila ropes have run satisfactorily for a great many years without renewal.

# LEGAL INTELLIGENCE.

## Franklin and Gould v. The Exeter Electric Lighting Company (Limited).

This case came before Mr. Justice North in the Chancery Division yesterday.

The plaintiffs are trustees for the debenture-holders, and state that the Company had entered into an agreement with the Exeter Corporation for the sale of their undertaking for £7,500, which agreement would take effect on the 30th inst. The only asset of the Company outside this sale consisted of certain book debts, and a few chattels worth about £1,000, making in all £8,500. The debentures amount to £12,000. The Company was in difficulties, and there were debts which it could not pay—one of the unsecured creditors was suing the Company—and under these circumstances the debenture-holders' trustees sought to enforce the security under the debenture deed, and to ask for the appointment of a Mr. Knill as receiver with power to manage until the sale to the Corporation was effected. No opposition was offered by the Company, and judgment was given for the amount of plaintiff's security. Mr. Knill was appointed receiver and manager.

# TRADE NOTES AND NOTICES.

*[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]*

**SPECIAL NOTICE—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d. abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations.**

## NEW BOOKS AND EDITIONS.

*The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. The NEW EDITION is NOW READY. Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either *singly* at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d. Will be ready next week.

**"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.**

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell, with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

'THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition now ready. Price 2s., post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from Notes made by Mr. Parshall in his capacity as chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

TENDERS INVITED.—The Corporation of Leeds require tenders for an electrical installation sufficient for working by the overhead system a double track of tramway seven miles in length. The work is divided into seven contracts, details of which will be found in our advertisement columns. Tenders have to be sent in to the Town Clerk, Town Hall, Leeds, not later than June 20th, and particulars, plans, &c., can be obtained from the City Engineer, Municipal Buildings, Leeds, or from Dr. John Hopkinson, F.R.S., 5, Victoria-street, Westminster, London, S.W.

——— The Shoreditch Vestry invite tenders for the supply of insulated conduits, cables, switch and fuse boards and all sundry fittings and materials for installing the electric light in their new dust destructor and electricity supply station. Specifications, &c., may be obtained from the consulting engineers, Messrs. Kincaid, Waller and Manville, 29, Great George-street, Westminster, S.W., and tenders must be sent in to Dr. H. Mansfield Robinson, Vestry Clerk, Town Hall, Old-street, E.C., by 4 p.m. on Tuesday, the 16th inst. Further particulars are given in our advertisement columns.

——— The Corporation of Burnley invite tenders for the supply and delivery of armoured concentric underground cables. Specifications, &c., may be obtained from the Borough Electrical Engineer (Mr. W. R. Wright), and tenders must be sent to the Chairman of the Electric Lighting Sub-Committee, Town Hall, Burnley, by Wednesday, the 24th inst. Some additional information appears in our advertisement columns.

——— The Directors of the Caledonian Railway Company require tenders for twelve months' supplies of a quantity of stores, particulars of which are given in our advertisement columns. The requirements include copper rivets, &c., india-rubber, galvanised wire, telegraph and electric appliances, tools, bolts and nuts, &c. Specifications and forms of tender and other information can be obtained from Mr. Jas. Lorimer, Superintendent of Stores, Charles-street, St. Rollox, Glasgow. Tenders have to be sent in to the Secretary (Mr. J. Blackburn), at the Company's offices, 302, Buchanan-street, Glasgow, by Monday, the 15th inst.

——— Owing to the impending expiration of the concession of the Jamaica Street Car Company, who own about 12 miles of horse tramways in Kingston, tenders are invited for a licence to establish and work a system of rapid transit in the island of Jamaica. Plans, &c., can be seen at the office of the Crown Agents for the Colonies, Downing-street, S.W. Tenders to the Clerk of the Privy Council, Kingston, Jamaica, by July 31st.

——— Tenders are required for the supply and erection of a 92-unit *continuous-current dynamo*, and a 3½-unit combined steam engine and dynamo. Tenders to Learoyd Bros. and Co., Milnsbridge, Huddersfield, by noon of 19th inst.

——— The Municipal Authorities of Benevento invite tenders for the concession for *supplying* electric current for public and private lighting. Tenders to the Consiglio Comunale di Benevento (Italy) by the 20th inst.

——— The Municipal Authorities of Ocaña are inviting tenders for the concession for the electric lighting of the town for ten years. Tenders to El Secretario del Ayuntamiento de Ocaña (Toledo), Spain, by the 30th inst.

——— The Paris Municipal Authorities require tenders for the supply of a dynamo for the Buttes-Chaumont central station. Tenders to be sent to l'Hotel de Ville, Paris, by the 17th inst.

——— The Belgian State Railway Authorities require tenders for the supply and erection of the necessary plant and fittings required for the electric lighting of the fifth section of the locomotive works at Malines. Tenders to be sent to the Bourse, Brussels.

——— The Municipal Authorities of Alberique require tenders for the electric lighting of the town for ten years. Tenders to El Secretario del Ayuntamiento de Alberique (Valencia), Spain, by the 12th inst.

TENDERS ACCEPTED.—The Electric Light Committee of the Aberdeen Town Council have decided to accept the tender of Messrs. M'Kinnon and Co. for the supply and erection of boilers, pumps and feed-water heaters at the electricity supply station, at £2,995. The Committee have also let out separate contracts for the mason, joiner, plasterer, plumber and painter, and slater work, in connection with the extension of the station. The total of these amounts to £3,148. 16s.

——— Messrs. Richard Crittall and Co. have secured the contract for the electric installation at the West Sussex County Asylums, Chichester. The contract includes plant, battery of accumulators, wiring and fittings. The consulting engineers for the work are Messrs. Massey and Allpress.

——— At the last meeting of the Hampstead Vestry it was reported that the Brush Company were not prepared to carry out the portion of their tender for the supply of additional plant at the electricity station unless their tenders for the steam alternator and switchboard were also accepted, and under these circumstances it

Digitized by Google

was decided to accept the tenders of Messrs. J. E. and S. Spencer (for tank and appurtenances at £395) and Wright's Patent Heater Condenser Company (for feed-water heater and steam pipes at £967) in lieu of the Brush Company's original tender.

TENDER ACCEPTED.—Some time ago the Colchester Town Council invited tenders for erecting and equipping electricity supply works, and tenders were received from Messrs. Christy Bros., the Brush Company, Siemens Bros. and Co., and the Electric Construction Company. The figures for carrying out the necessary works and for loaning temporary plant for lighting the military hospital were respectively £13,092 and £147, £12,076. 15s. and £186, £11,477 and £375, and £10,675 and £257. 10s. The Electric Light Committee now recommended that the tender of the Electric Construction Company be accepted, and that application be made to the Local Government Board for sanction to borrow £15,000 for carrying out the scheme, and this has been agreed to.

SALE BY AUCTION.—Messrs. Percy Huddleston and Co. notify in our advertisement columns that they will sell by public auction, on Tuesday, the 16th inst., the contents of the Acme and Immisch Electric Works, Ferdinand-street, Chalk Farm, N.W., comprising dynamos, motors, electrical instruments and apparatus, engines, boilers, &c, and lathes, punching and shaping machines, tools, &c.

APPOINTMENT.—At Wednesday's meeting of the Burnley Town Council the appointment of Mr. W. R. Wright as borough electrical engineer was confirmed. The salary is £200 per annum, to be increased to £250 at the end of twelve months.

APPOINTMENTS VACANT.—The Leyton Urban District Council invite applications for the post of resident engineer to the electric lighting installations now in course of construction. Some further particulars are given in our advertisement columns.

——— The Corporation of Lincoln, invite applications for the position of electrical engineer. Salary £300 per annum. Applications to Mr. H. K. Hebb, by Saturday, 6th inst.

LIQUIDATIONS.—A petition has been presented by Messrs. B. Verity and Sons for the compulsory winding-up of the Coventry Electrical Engineering Company (Limited), and will be heard at the County Hall, Coventry, on the 9th inst.

——— It has been decided to wind up the London Refuse Steam Generator and Electrical Power Corporation (Limited), and Mr. C. W. Grimwade, 38, Coleman-street, E.C., has been appointed liquidator.

THE "ENGINEERING MAGAZINE."—The contents of the June number of this magazine include: "The Fruits of Fraudulent Railroad Management," by J. Selwin Tait; "The Absence of Facts about the Nicaragua Canal," by Charles B. Going; "Relation of Electrical to Mechanical Engineering," by Elias E. Ries; "The Domestic Architecture of Washington City," by Glenn Brown; "Recent Improvements in Gold Milling," by H. M. Chance; "Modern Machine Shop Economics" (III.) by Horace L. Arnold; "The Electric *versus* the Hydraulic Elevator," by W. Baxter, jun.; "Bank Revetment of the Mississippi River," by H. St. L. Coppée; "Minor Mineral Products of the United States" (II.), by David T. Day; and "Quackery in Engineering Education," by E. H. Williams, jun., D. C. Jackson, H. K. Landis and George L. Hoxie. The usual exhaustive review of the World's Press is also given. This number, as well as all the back numbers, may be obtained at the offices of the European Edition, 1, 2 and 3, Salisbury-court, Fleet-street, London.

"CASSIER'S MAGAZINE."—The contents of the June number of this Magazine include "Electric Current Supply from Central Stations," by John W. Lieb, junr.; "Steam Superheating," by W. H. Patchell; "Steam Raising," by Bryan Donkin; "The Value of Engineering Publications in Law Suits," "Compressed Air for Street Railroads," "Making Steel Forgings in America," "Economic Workshop Output," "Modern English Traction Engines," and "Peat Fuel in Germany."

---

BALLYMENA.—A special Electric Lighting Committee has been formed by the Town Commissioners.

BANGOR.—The City Council apparently intend to proceed with their electric lighting scheme, and a formal resolution has been passed in favour of making application to the Board of Trade for a Provisional Order.

BREST-ST. PIERRE CABLE.—This cable being now repaired, telegrams can be forwarded by the "P. Q." route.

BRIGHTON.—Col. J. O. Hasted, R.E., held a Local Government Board inquiry on Tuesday into the application of the Town Council to borrow £35,900 for electric light extensions. The Corporation was represented by Mr. W. P. Boxall and the Borough Electrical Engineer (Mr. Arthur Wright). Mr. Boxall gave particulars of the progress of the electricity works and of the various extensions that had been carried out. Having regard to the rapid increase in the demand for current, it was obvious that further extensions were necessary, more particularly as the Corporation had decided to supply electric current throughout the streets of the town, and the greater part of the present loan would be utilised for this purpose. Mr. Arthur Wright, who gave particulars of the proposed extensions, stated that the idea was to have public electric lighting in every street where mains were laid. The works included extensions and new machinery, new mains, &c. There was no opposition.

CHAPEL LIGHTING.—Brunswick Chapel, Sheffield, is to be wired for the electric light.

DUBLIN SOUTHERN TRAMWAYS.—The tramways of the Dublin Southern Company have been certified by the Board of Trade as fit for public traffic.

DUNDEE.—The accounts of the Electricity Department for the past year show a profit of £1,126. 15s. 1d. At the meeting of the Council, on Friday last, Mr. Treasurer Ritchie moved the abolition of meter rents and the adoption of a uniform system of discounts for the gas and electricity departments. After a long debate the motion was agreed to.——As the result of a conference between sub-committees of the Town Council and Harbour Board, it has been decided to introduce a scheme for electrically controlling the clocks of the town. An experimental installation is to be at once erected.——An interesting epitome on the progress of electric lighting in Scotland was recently given by one of the members of the firm of Lowdon Brothers, of Dundee, to a local journal. Mr. Lowdon admits that the electric light made but slow progress in Scotland until the introduction of the incandescent lamp, since which time it has gradually forged ahead, and is now being taken up in real earnest, especially amongst mill-owners, and in spinning and weaving factories. This is noticeable all over the North. Mr. Lowdon has to record very little motive power work by electricity in Scotland, and looks forward to a speedy improvement in this direction.

ECCLES.—Unless satisfactory indications were given that the Town Council intended to proceed with their electric lighting scheme the Provisional would expire, and consequently the Electric Lighting Committee have notified the Board of Trade that borrowing powers are being sought in order that the provisions of the Order may be carried out.

A Local Government Board inquiry was held on Wednesday last by Mr. G. W. Willcocks into the application of the Town Council to borrow £20,000 for electric lighting purposes. The Town Clerk, Mr. G. W. Bailey, appeared in support of the application, while Mr. Overend Evans represented a body styled "the Eccles Property Owners' Association." The Town Clerk detailed the steps that had been taken by the Council in preparing an electric lighting scheme. Tenders had been invited in order to ascertain its probable cost, and the offer of the Manchester Edison-Swan Company for £13,792 was considered most suitable; buildings, &c., would come to £4,969, making a total of £18,761. The scheme involved the lighting of all the streets in the borough, and it was proposed to adapt the present street lamps for incandescent electric lighting. Mr. S. T. Clirehugh, the consulting engineer, gave technical details of the scheme. He estimated that the annual working expenses, interest, repayment of the sinking fund, &c., would amount to £2,066. The capacity of the proposed works would be 750 20 c.p. lamps for public lighting, and 3,750 16 c.p. lamps for private lighting, and if all these lamps were on order there would be a satisfactory profit. The witness was cross-examined at some length by Mr. Evans and other opponents of the scheme as to certain details of the scheme now proposed to be carried out, with a view to comparison between this and a scheme proposed by Dr. J. Hopkinson some time ago for lighting the Eccles district. Evidence was also given by Mr. W. P. J. Fawcus, and the inquiry was adjourned.

As if to encourage the local authority to proceed with the scheme, Messrs. Ermen and Roby, who have decided to introduce the electric light at their extensive works, have written asking if the Council would be prepared to supply current to about 1,500 16 c.p. lamps. If the Council do not proceed with their electric lighting scheme the firm intend to put down an independent plant.

EXPORTS OF ELECTRICAL APPARATUS AND MATERIAL.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from May 28th to June 2nd, with the ports of destination:—

*Australasia*—Albany, £38; Brisbane, £1,411 (submarine cable); Melbourne, £407 (including £294 telegraph material); Otago, £46; Perth, £147; Sydney, £706; Wellington, £19. *Ceylon*—Colombo, £107. *Egypt* Suez, £25. *Holland*—Amsterdam, £60; Rotterdam, £10: *India*—Bombay, £63. *Japan*—Yokohama, £138. *Russia*—St. Petersburg, £33. *South Africa*—Cape Town, £180; East London, £233; *Straits Settlements*—Singapore, £34. *Sweden*—Gothenburg, £135 (telegraph wire).

*Foreign made Electrical Apparatus and Material.*—Foreign made goods have been exported from this country as follows:—

*Australasia*—Melbourne, £36. *Italy*—Leghorn, £43 (electric meters). *Siam*—Bangkok, £1,550.

Digitized by Google

ELECTRICITY IN MINING.—As an indication of the advances which are being made in the application of electricity to mining, it is now becoming the general practice to insert in the prospectuses of gold mines for which capital is invited, full particulars regarding actual or projected electrical installations at the mines, as a further inducement, we presume, to the public to subscribe.

ELECTRIC PUMPING MACHINERY.—In the annual report of Young's Paraffin Light and Mineral Oil Company (Limited) the Directors' estimated capital outlay during the current year includes a sum of £2,500 for electric pumping machinery at Polbeth.

EXETER.—The formal transfer of the Exeter Electric Light Company's undertaking takes place on the 30th inst., and the Council anticipate an increased demand as soon as they are in a position to give a continuous supply of current. The condition of the plant at the station is at present engaging the attention of the Electric Lighting Committee.

INTERNATIONAL TELEGRAPHIC CONFERENCE.—A slight amendment is necessary to the list of names given on pages 158 and 159 of our last issue. The delegates to the conference representing the Post Office, Cape Colony and Natal are as given in our list, except that they act jointly, and that Mr. R. J. Mackay acts as secretary. The delegate for India is Mr. S. P. W. V. Luke, C.I.E. Mr. R. T. Brown's name should be omitted as representing the West India and Panama Telegraph Company.

LAHORE (INDIA).—The municipal authorities of this town are at present considering the question of the erection of an electricity supply station. Plans and estimates have already been prepared and submitted to the local Legislative Council.

LEEDS.—The Yorkshire House-to-House Company recently offered to supply the Corporation with electrical energy for working the tramways, and to put down special plant at their station in Whitehall-road for the purpose. Under a contract for a short period they would supply 300,000 units per annum at 2·3d. per unit, this price to be materially reduced if the term of the contract were extended, or an increased quantity of current be required. As an alternative the Company suggest that the Corporation should provide the special plant and apparatus, which could be of a portable nature and suitable for use at any permanent station the Corporation might erect.

LINCOLN.—The Town Council have purchased a piece of land as a site for an electricity generating station, in connection with which application is now being made for a Provisional Order.

LLANELLY.—Mr. J. C. Howell has submitted an estimate to the District Council for the electric lighting of the principal streets of the town. The matter is being considered by the Property Committee.

MANCHESTER.—The Special Tramways Committee have presented an elaborate report on the purchase of the local tramways by the City Council. The Glasgow, Blackpool, Plymouth, Leeds, and Huddersfield municipal tramways have been inspected, and the condition of working noted; but the Committee recommend that the further consideration of the matter be postponed till 1898, when the lease of the first portion of the lines expires, and in the meantime that the Corporation obtain parliamentary powers to work the tramways. The report was discussed at considerable length at the Council meeting on Wednesday, several members contending that the Council ought to take over the lines as soon as possible, and to introduce electric traction throughout the system. The last paragraph was amended so as to read that parliamentary powers be obtained in the next session of Parliament, and in this form was agreed to.

MATLOCK.—A telephone exchange has been established in this town.

OLDHAM.—The accounts of the Electric Lighting Committee for the year ended March 25th have been published, and are of a highly satisfactory character. The total capital expenditure of the year amounted to £6,289. 9s., gross revenue to £3,847. 13s. 4d., and expenditure to £1,577. 17s. 9d., a balance of £2,269. 15s. 7d. Interest on loans came to £813. 8s. 4d., and sinking fund instalment to £608. 12s. 7d., leaving a net profit of £847. 14s. 8d., which with £902. 3s. 7d. brought forward, makes a total of £1,749. 18s. 3d. to be carried forward. During the period under review, 179,966 units have been generated and 147,432 have been sold, increases of 95,599 and 78,434 units respectively on the previous year. There were 113 customers (representing an equivalent of 11,830 8 c.p. lamps) connected, an increase of 58 customers and 4,890 8 c.p. lamps respectively for the year. The maximum demand was on January 6th, the load at the station being indicated at 251 kilowatts, an increase of 116 compared with the previous year. January 6th was also the record day as to the number of units sold, the figures being 1,232 units, against 641 last year. The Committee recommend that after March 25th last the price for current used by private customers in excess of two hours' daily average maximum demand shall be reduced to 4½d. per unit, and for all current supplied to street lamps 4d. per unit. Application has been made for additional borrowing powers to the extent of £15,000. The Committee also report that two additional engines and dynamos of 200 H.P. each have been erected, and 1,187 yards of mains have been laid during the year.

PACIFIC CABLE.—Reuter's agency, under date May 29th, reports that "the Committee of Commerce of the United States House of Representatives has authorised a report to be presented in favour of the Substitute Cable Bill, which provides that the Postmaster-General may contract with the Pacific Cable Company of New York for the construction of a cable from the United States to Hawaii, Japan, and China, via the Midway Islands. It is provided that the President may control the line in time of war. The grants and subsidy for the new cable amount to $100,000 yearly, with the right of way over United States territory."

PERSONAL.—Mr. J. Harrhy, Superintendent of the Eastern and South African Telegraph Company at Benguella, West Africa, is leaving the Coast for England.

POLICE.—The journalist named Norman M'Leod who was charged at Marlborough-street Police Court with obtaining credit to the extent of £35. 10s. from Mr. R. Aylmer without informing him that he was an undischarged bankrupt, has decided to pay the money to the prosecutor, a course to which the magistrate has assented.

POPLAR (LONDON).—The Board of Works have decided to apply to the Board of Trade for an extension of time for complying with the terms of their Provisional Order.

ROTHERHITHE (LONDON).—The London Electric Supply Corporation have applied to the Vestry for leave to lay mains in the Rotherhithe New-road and Bush-road.

SUNDERLAND.—The Electric Light Committee recommend the Town Council to reduce the price of electrical energy for motive power purposes from 3½d. to 2½d. per unit. The Committee have also formulated a scheme for the further extension of the mains.

ST. HELENS.—The Local Government Board have sanctioned the borrowing of £10,000 by the Town Council for electric lighting purposes. The Council consider the period over which the repayment of the loan is spread inadequate, and have instructed the Town Clerk to apply for an extension.

SWANSEA.—On the recommendation of the Markets Committee, it has been decided to light the new Corporation Market electrically.

TUNBRIDGE WELLS.—The statement of accounts of the Corporation's electricity works for the period ended March 31st last is issued. Since the commencement of supply on August 7, 1895, 72,072 units of current have been generated, 60,571 of which have been sold, and 2,011 used on the Corporation's works. The total number of lamps connected at the date of the report is 7,066 incandescents and 21 arcs. The total capital raised is £25,000, and as no payment is due upon these borrowings until September 25th next no charge is made in the accounts for interest or sinking fund. The total capital expenditure to March 31st is £15,408. 18s. 9d., leaving an unexpended balance of £9,591. 1s. 3d. The revenue account shows a net profit of £737. 13s. 7d., subject, of course, to a proportion of interest and sinking fund charges.

WELLS.—The Town Council have decided to instruct Dr. John Hopkinson to prepare plans and specifications for the establishment of electricity supply works. This decision has been come to owing to friction with the Gas Company as to the cost of obtaining Parliamentary powers for the purchase of the gas works by the Council.

WORTHING.—The Town Council are endeavouring to obtain an extension of time for carrying out the provisions of their Provisional Electric Lighting Order.

## PATENT RECORD.

*A record of Applications for Patents and Patent Specifications Published is compiled for this journal by* MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

### APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

May 11, 1896.

9,959. W. H. LANDER. Dublin. Improvements in electrical arc lamps.

9,960. F. HELMAN and J. CARROLL. Liverpool. Improvements in electric bell communication.

9,964. G. H. NISBETT. Liverpool. Improved electric cables.

# COMPANIES' MEETINGS AND REPORTS.

## West Coast of America Telegraph Company (Limited).

The nineteenth ordinary general meeting of this Company was held last Friday, under the presidency of Mr. J. Denison Pender.

The SECRETARY (Mr. Frederick L. Robinson) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: In moving the adoption of the report and accounts I will deal with the report and with various items in the accounts. The gross income for the past year amounted to £32,930, as against £21,754, an increase of £11,176. This includes, however, as I will presently explain, a rebate of £3,140 made to this Company out of the international traffic receipts by two of the associated companies. The real income earned was therefore £29,790, or an increase of £8,036 for the year. During the early part of last year the traffic receipts were sufficiently favourable to justify the hope that the year's working would result in our making both ends meet, but later on the local traffic fell off, mainly in consequence of the stagnation in the nitrate trade, and this state of things continued during the remainder of the year, so that it is only owing to the rebate that we are able to meet our working expenses and also the interest on the debentures. The expenses for the year were £776 in excess of those for 1894, the increased expenditure being principally due to the higher sterling value of the Chilian dollar. This is especially the case in salaries of native employés, rent and taxes, &c., which are paid in dollars, their value being taken at the rate of exchange of the day. The London office expenses, the working expenses of your repairing steamer "Retriever," and the cost of maintaining the cables and land lines are much about the same as in the previous year. The chief item of expense this year has been a new boiler for the repairing ship. We have been obliged to send out a new steel boiler to the steamer "Retriever" to replace the old boiler, which, notwithstanding the care and attention of the engineers of the steamer—to whom every credit is due—was becoming inefficient after being in use for 17 years—an exceedingly long time, I believe—and as it is poor economy to try and save money by allowing our property to deteriorate, it was considered necessary by your Directors that a new boiler should be put in the ship. This was made in England and shipped to Callao; the total cost, including freight, taking out the old boiler and fitting the new one in its place, was £1,978. The steamer was also fitted with new coal bunkers, funnel and ventilators, and is now considered to be in first-class condition, and, barring accidents, fit for service for many years to come. With regard to repairs and renewals, during the past year the shore ends of the cable at Arica had to be renewed, and a bad fault cut out near Iquique, caused by the foundering of a vessel, which went down on the cable and damaged it very much. The Valparaiso-Talcahuano cable was interrupted by a submarine landslip, and repaired in July. I have given you, I think, full particulars in regard to the Report and Accounts, and before moving their adoption, I will, as briefly as possible, speak of our present position. The completion of the arrangements among nitrate producers to restrict the output for a term of years, and the disappearance of the friction hitherto existing between Chili and Argentina, will no doubt tend towards a revival of trade on the West Coast and have a beneficial effect on our local, as well as on our international traffic. The latter class of traffic has, I am happy to say, grown steadily since the opening of the lines between Valparaiso and Buenos Aires, in March, 1894; and in regard to the working of this line, which belongs to the Pacific and European Telegraph Company, and of the connecting cables of the associated companies, I may mention that the result of the University Boat Race last March was transmitted from London to Valparaiso, a distance of nearly 8,000 miles, in 45 seconds, and on to Iquique and Lima a few seconds later. Such a magnificent result was not achieved without preparation, but it serves to show the perfect working of our telegraphic system between this country and Chili and Peru. Of course, I do not mean to say that a message in the ordinary course could be sent at that pace, because special arrangements were made for it, but we often send messages such as the result of the Boat Race and the winner of the Derby—or something of a similar sort—really to see what can be done when arrangements are made to carry a message right through without hindrance; and when you come to think of the different transmissions that the message has over the course of the 8,000 miles, I, who know a great deal about it, having been associated with telegraphy for a great many years, consider it almost a marvel. Before concluding, I wish to make it very clear to the shareholders that the special rebate which relieved them of what would have been a loss of £3,140 on last year's working must not be taken to mean that in the event of a deficit this year it will be wiped off in a similar way. Our normal proportion of the international traffic receipts was fixed at the commencement by the associated companies—that is to say, we all agreed temporarily to certain rates when the Pacific and European line was opened, because four companies have to participate in the through rate, of which this Company is one. It was fully anticipated at the time that arrangement was come to that our share of the pool, added to our local traffic receipts, would be sufficient at least to pay our working expenses and the debenture coupons, if not to leave a balance over: but last year's working, no doubt due to temporary causes, did not realise these anticipations, and under the circumstances, and having regard to the general policy which resulted in the formation of the Pacific and European Telegraph Company, and the alliances thereunder, the special rebate in question was allowed to this Company. It must, however, be clearly understood that it was only allowed for the year 1895, and that it is quite possible it may be declined for the year 1896. However, we can only hope that the traffic may increase and that we shall be able of ourselves to make both ends meet. So far, however, the traffic this year remains pretty much as it was last year, but when you compare last year's figures with those of 1894 it is very satisfactory to find that we have an increase of over £8,000, and that we are really getting within measurable distance of making both ends meet. I think that is all I have to say, but if any one wishes to ask any questions, I shall be happy to answer them if it is in the interest of the Company that I should do so. I now move—

"*That the report and accounts for the year ended December 31st, 1895, now presented, be received and adopted.*"

Mr. FREDERICK WALTERS briefly seconded the motion, which was at once carried unanimously without discussion.

The CHAIRMAN proposed the re-election of Mr. Walters to his seat at the board.

Mr. PACE seconded the resolution, and remarked that everything in connection with the Company was now in such excellent order that with a better exchange and improved trade, the Company would enjoy a certain share of prosperity, although, perhaps, not its former prosperity.

The resolution was carried unanimously.

Mr. WALTERS, after acknowledging his re-election, proposed the re-appointment of Mr. Pender.

Mr. CLAY seconded the motion, which was carried unanimously.

The CHAIRMAN, in acknowledging his re-election, stated that there were only two Directors of the Company, and he believed that by their articles of association two members of the Board had to retire every year. His colleague and himself, therefore, had to go out of office every year, but it was hardly worth while at the present time to appoint another Director, the fees of the third Director going into the coffers of the Company.

The auditor, Mr. John Francis Clarke, having been re-elected,

Mr. LAMONT proposed a vote of thanks to the Directors for their management of the Company's affairs in the past year, and to the Chairman for presiding. He wished that the statement submitted to them had been more satisfactory for both Directors and shareholders, and that the Chairman could have held out a hope to them of a dividend in the current year.

Mr. PACE, in seconding the motion, observed that they had to thank the Directors for their care of the Company's interests, and in having succeeded so far in getting the Company "round the corner."

The motion was carried unanimously.

The CHAIRMAN, in reply, said he believed that everything that was possible to be done was being done by them. He would be glad if they would allow him to include in the vote of thanks the staff both in London and abroad.

Mr. LAMONT: Certainly.

The CHAIRMAN: Those gentlemen, he was sure, worked as hard as they possibly could to promote the welfare of the Company.

The proceedings then terminated.

## West African Telegraph Company (Limited).

The report of the Directors of this Company for the year ended December 31st last will be presented to the meeting of shareholders to be held at Winchester House, London, E.C., on Thursday next, at 12:15 o'clock.

The Company's revenue amounted to £74,333. 4s. 9d., against which £17,474. 10s. 2d. is charged for ordinary expenses, and £6,298. 1s. 10d. for expenditure relating to repairs of cables, &c. After providing for income tax, &c., there remains a balance of £49,660. 2s. 2d. From this balance £11,322. 17s. 10d. is deducted for interest on debentures, and £12,333. 6s. 8d. for sinking fund, and £15,000 has been put to the general reserve fund. An interim dividend for the six months ended June 30th last of 2s. per share has been paid, and the Directors now recommend a final dividend of 6s. per share, making 4 per cent., free of income tax, for the year ended December 31st. £1,760. 5s. 8d. is carried forward.

Sir Henry C. Mance, C.I.E., offers himself for re-election as Director, as do the auditors, Messrs. Deloitte, Dever, Griffiths and Co.

## Electric Traction Company (Limited).

The report of the Directors of this Company for the year ended December 31st will be presented to the shareholders this day (Friday).

The allotment of the Company's share capital, the whole of which has been subscribed, took place on June 18, 1895. The Deferred shares are fully paid, and £2 per share has been paid on the Ordinary shares. On June 18, 1895, the Company entered into a contract with the Central London Railway Company for the acquisition of the necessary land and the construction and equipment of the railway with all its appurtenances to the satisfaction of the railway company's engineers. Immediately after the execution of this contract the Directors proceeded with the compulsory acquisition of the properties required for the station sites and the generating depot at Shepherd's Bush, with the result that thus far upwards of three-fourths of the total number of claims have been settled or adjudicated upon. This work is being pushed forward as quickly as possible, so that possession of station sites may be obtained to enable the work of construction to be commenced not later than July 1st next.

The line from Shepherd's Bush to the Bank has been divided into six sections, and on February 19th last, a selected number of firms, all of whom were approved by the engineers to the railway company, were invited to tender for the construction of the tunnels and shafts and incidental work in respect of these six sections. A considerable number of tenders having been received, the Directors have entered into the following sub-contracts:—Shepherd's Bush to Marble Arch, Mr. J. Price; Marble Arch to Post Office, Messrs. Walter Scott and Co.; Post Office to Bank, Mr. G. Talbot. The arrangements with regard to the station at Liverpool-street are progressing satisfactorily. The prices at which these sub-contracts—which cover the principal part of the work of construction—have been let, and the cost of acquiring the station sites are fairly in accord with the estimate formed as to the cost of the undertaking, and confirm the Directors' anticipation that the construction and equipment of the Central London Railway will be carried out within the contract price, with a fair margin of profit to this Company.

## NEW COMPANIES, STATUTORY RETURNS, &c.

**ELECTRICAL COPPER COMPANY (LIMITED).**—This Company was registered on May 23rd, with a capital of £500,000 in 150,000 Preference and 350,000 Ordinary shares of £1 each, to acquire certain patents and inventions relating to the industrial electrolysis of metals, to acquire any other patents, licences, concessions, &c., relating to the manufacture or treatment of copper or other metals, or substances, and to use, develop, work and deal with the said patents and patent rights. The first subscribers, with one share each, are:—H. M. Matheson, C. A. Fould, E. Dumoulin, A. McKechnie, R. M. Moir, R. Lorimer and L. S. Johnson. The first Directors are:—H. M. Matheson, A. Fould, W. Jacks, A. McKechnie, R. M. Moir and E. Dumoulin.

**MALAGA ELECTRICITY COMPANY (LIMITED).**—This Company was registered on May 23rd, with a nominal capital of £57,000 divided into 10,000 Ordinary shares of £5 each, and 7,000 Deferred shares of £1 each, to enter into an agreement with Messrs. Zulueta and Co. to carry on the business of an electric lighting company in all its branches at Malaga (Spain), or elsewhere; to construct, lay down and fix all necessary cables, wires, lines, accumulators, lamps and works; to generate, accumulate, distribute and supply electricity, and to carry on the business of electricians, mechanical engineers, suppliers of electricity for light, heat or motive power purposes, manufacturers of and dealers in electric accumulators, lamps, lamp-posts, electric elevators, carbons, steam and other engines, turbines, water-wheels &c. The first subscribers are:—J. M de Zulueta, merchant (1,900 shares), A. Fowler, engineer (1,250 shares), Louis Floersheim, merchant (1,000 shares), F. S. Isaac (1,000 shares), A. Hill, (1,000 shares), T. W. Bernard (400 shares), and R. C. Wyatt (100 shares). The first Directors are Messrs. R. C. Wyatt, G. von Chauvin and A. Fowler.

**SIMPLEX ELECTRIC TRAMWAY CONDUIT SYNDICATE (LIMITED).**—This Company was registered on May 29th, with a capital of £30,000 divided into 5,000 "A" and 25,000 "B" shares of £1 each, to acquire from Mr. James B. Atherton, Rainhill, Lancs., the benefit of a certain invention in relation to improvements in the means of and apparatus for distributing and collecting electricity for the propulsion of vehicles, and to carry on the business of tramway and railway proprietors, manufacturers of accumulators, dynamos, trams, locomotives, &c., electricians, electrical engineers, electrical contractors and suppliers of electricity. The first subscribers, with one share each, are:—James B. Atherton, manufacturer, T. Snape, J.P., A. Adam, J. Atherton, R. Watson, J. Monkhouse, A. Wilkinson and R. Sumner. The first Directors are:—E. K. Muspratt, A. Adam, T. Snape and James B. Atherton.

**SOUTHERN CROSS EXPLORERS (LIMITED).**—This Company was registered on May 28th, with a nominal capital of £60,000 in £1 shares, to carry on, amongst other businesses, that of an electric light and power supply, telephone or telegraph company in all or any of its branches.

**QUEEN ANNE'S RESIDENTIAL MANSIONS AND HOTEL COMPANY (LIMITED).**—This Company was registered on May 27th, with a capital of £250,000 in 35,000 Preference and 15,000 Ordinary shares of £5 each, to acquire amongst other things the business, undertaking and assets of the Queen Anne Mansions Electric Light and Heating Company (Limited), and to carry on the business of an electrical engineering, electric lighting and power supply company in all or any of its branches. The first Directors are:—H. Bennett, J. Cator, J. Newmarch, Lord Berkeley Paget, E. Rawlings and Col. R. Vivian.

## CITY NOTES.

**MEMORANDA**—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 31½d. per oz. (June 4th). Consols (2¾ per cent.) 113¼—113⅜ for money, 113⅜—113½ for account; 2½ per cent. 106¼—106½ (June 4th). Stock Exchange Settling Days: Consols, July 1st; Stocks and Shares Continuation Day, June 10th; Ticket Day, June 11th; Pay Day, June 12th; Mining Share Carry-over Days, June 9th and 23rd.

**AKTIENGESELLSCHAFT ELEKTRICITATSWERKE VORMALS O. L. KUMMER AND CO.**—A dividend of 8 per cent. for the past year has been declared by this Company. The capital has been increased from £75,000 to £125,000.

**CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).**—The traffic returns of this Company for the week ended May 31st were £842, against £929 in the corresponding week of 1895, a decrease of £87. The total receipts for the half-year amount to £20,535, against £20,533 for the corresponding period of 1895, an increase of £2.

**CROMPTON AND CO. (LIMITED).**—Mr. John Trotter has joined the Board of Directors of this Company, and has been elected Chairman, in place of Viscount Emlyn, who resigned that position on being elected Chairman of the Great Western Railway Company.

**DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).**—The estimated traffic receipts of this Company for the month of May are £2,396.

**EASTERN TELEGRAPH COMPANY (LIMITED).**—The traffic receipts of this Company for the month of May, 1896, amounted to £73,853, against £68,382 in the corresponding period last year.

**EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).**—The traffic receipts of this Company for the month of May, 1896, amounted to £50,256, and to £44,620 in the corresponding period of 1895.

**ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).**—The Directors of this Company have decided, subject to audit, to recommend the payment of a further dividend upon the Ordinary shares at the rate of 30 per cent. per annum for the six months ended May 31st, making, with the interim dividend at the rate of 10 per cent. per annum already paid, a total dividend of 20 per cent. for the year, and also to recommend a dividend of £20 on each Founders' share for the year. The trustees for the Founders' shares reserve fund propose to distribute to the holders of such shares a sum of £20 per share for the year out of the proceeds of investments sold and dividends received in respect of the Founders' reserve fund, making, with the before-mentioned dividend, a total distribution of £40 on each Founders' share. The dividends, &c., are payable on the 19th inst. The transfer books and register of members will be closed from the 5th to the 18th inst. inclusive.

**ELECTRIC AND POWER SCHEMES IN VICTORIA.**—The Hon. Agar Wynne, ex-Postmaster-General of Victoria, and Mr. J. A. Dawson (late Lecturer on Electrical Engineering at the Ballarat School of Mines in the same Colony) are now in London in connection with a scheme of electric lighting and power transmission. It is proposed to consolidate several Victorian supply companies into one large concern. Electric lighting is well established in the Australian Colonies, and only requires developing. The Victorian Government has recently passed an Act to facilitate and regulate the supply of electricity, which has considerably strengthened the position of companies by granting them concessions extending over a term of 25 or 30 years. This Act was framed by the Hon. Agar Wynne during his term of office, and is the first attempt at legislation on the subject in the Colonies. The gentlemen named have, we are informed, full powers to act for the companies interested, and may be communicated with at the Langham Hotel, Portland-place, W.

**HELIOS ACTIEN-GESELLSCHAFT FUR ELECTRISCHE LICHT UND TELEGRAPHEN-BAU.**—At the recent general meeting of this Company it was decided to issue £50,000 Four per Cent. Debenture stock, for the purpose of acquiring a fresh site for the erection of new workshops.

**LIVERPOOL OVERHEAD RAILWAY COMPANY.**—The traffic receipts of this railway for the week ended May 31st amounted to £1,809. The amount for the corresponding week last year was £1,146; increase, £663.

**QUEEN ANNE'S MANSIONS LIGHTING AND HEATING COMPANY (LIMITED).**—The trustees to the debenture holders announce that they are prepared to pay in cash all interest accrued on the debentures to the 1st inst., and also one moiety of the principal, and, further, to deliver to the debenture-holders Second Debentures of the Queen Anne Residential Mansions and Hotel Company (Limited) for the other moiety.

**RUSTON, PROCTOR AND CO. (LIMITED).**—The report of the Directors of this Company for the year ended March 31st last states that there is a gross profit of £45,431 on the year's trading (including £3,065 brought forward), from which £4,411 has been deducted for depreciation of plant and machinery, Directors' fees, &c., leaving a net balance of £41,019. After paying interest on the £250,000 debentures, and the interim dividend of 5s. per share, there remains a balance of £24,144, and the Directors now propose to pay a dividend of 11s. per share, making, with the interim dividend, 8 per cent. for the year; £8,000 goes to the reduction of goodwill account. At the annual meeting of the shareholders on Wednesday, the report and accounts were agreed to.

**WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).**—This Company's traffic receipts for the week ended May 29th, after deducting 17 per cent of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,590.

**WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).**—The estimated traffic receipts of this Company for the half month ended May 31st are £2,818, against £2,620 in the corresponding period of 1895. The January receipts (estimated at £5,523) realised £5,624.

# THE UNIVERSAL STEAM ENGINE

(RAWORTH'S PATENT).

In consequence of the large and increasing demand which has sprung up for this Engine since its introduction to the public (see *Engineering* of 28th Feb., 1896), the Directors of the BRUSH ELECTRICAL ENGINEERING COMPANY have authorised a large EXTENSION of their WORKS. Building operations have commenced and will be completed in August in time to cope with the Autumn trade.

## UNDERGROUND MAINS.

## CALLENDER'S BITUMEN TELEGRAPH & WATERPROOF COMPANY, Ltd.

MANUFACTURERS OF

**ELECTRIC LIGHT CABLES, MAINS, CONDUITS AND ACCESSORIES.**

**Engineers and Contractors. Ironfounders and Coppersmiths. Makers of Lead Tube and Pipes. Bitumen Refiners**

**Head Office: 90, CANNON STREET, LONDON, E.C.**

Telephone No. 15133. Telegraph Address: "CALLENDER LONDON."

**Factory—ERITH MARSHES, KENT.**

**LIVERPOOL—Oldham Place, Renshaw Street. BIRMINGHAM—58, Water Street.**

**NOTTINGHAM—King John's Chambers, Bridlesmith Gate. GLASGOW—Great Western Road, Kelvinside.**

Also Contractors for underground Mains at ABERDEEN, COATBRIDGE, BURNLEY, LANCASTER, HUDDERSFIELD, SHEFFIELD, HULL, OXFORD HANLEY, CHELSEA, &c., &c.

The CALLENDER COMPANY is prepared to undertake the laying of Underground Mains, including all excavation and reinstatement of paving, building boxes feeder points, or transformer chambers, erecting lamp posts, pillars and all other accessories required for the complete equipment of the distribution network of a Central Station, for either HIGH or LOW TENSION with CONTINUOUS or ALTERNATING CURRENTS —

1. With Vulcanised Bitumen Cables laid solid in Bitumen.
2. Or Drawn into CALLENDER-WEBBER or CALLENDER-RAWORTH Conduits, or into Pipes.
3. With Lead-Sheathed Cables either Single Conductor, Concentric, or Triple Concentric, armoured and laid direct in the earth.

**Price 1s., post free 1s. 3d. Annual Subscription, 12s. 6d. post free, abroad 14s.**

## "THE ENGINEERING MAGAZINE."

An American Monthly Periodical, having an extensive sale and containing popularly-written critical articles on Electrical Engineering and Social Subjects by leading writers.

**CONTENTS OF THE JUNE ISSUE (No. 3, Vol. XI.).**

THE FRUITS OF FRAUDULENT RAILROAD MANAGEMENT.—J. Selwin Tait.
THE ABSENCE OF FACTS ABOUT THE NICARAGUA CANAL.—Charles B. Going.
RELATION OF ELECTRICAL TO MECHANICAL ENGINEERING.—Elias E. Ries.
THE DOMESTIC ARCHITECTURE OF WASHINGTON CITY.—Glenn Brown.
RECENT IMPROVEMENTS IN GOLD MILLING.—H. M. Chance.
MODERN MACHINE SHOP ECONOMICS. III.—Horace L. Arnold.
THE ELECTRIC VERSUS THE HYDRAULIC ELEVATOR.—W. Baxter, jun.
BANK REVETMENT OF THE MISSISSIPPI RIVER.—H. St. I. Coppée.
MINOR MINERAL PRODUCTS OF THE UNITED STATES. II.—David T. Day.
QUACKERY IN ENGINEERING EDUCATION. I.—E. H. Williams, jun. II.—D. C. Jackson. III.—H. K. Landis. IV.—George L. Hoxie.

Each issue of the Magazine also contains—

**A Complete Index of the Contents of the World's Technical Press.**

THE ENGINEERING MAGAZINE is profusely illustrated and forms a handsome six-monthly volume. A complete Index to the Contents of the Magazine from the Commencement will be forwarded post free on request.

**A Specimen Back Number will be forwarded on receipt of 6d. to defray postage, &c.**

**European Agent: GEO. TUCKER, Publisher, "THE ELECTRICIAN" PRINTING & PUBLISHING CO., Ltd.**
**SALISBURY COURT, FLEET STREET, LONDON, E.C.**

WILL SELL BY PUBLIC AUCTION,

**On TUESDAY, JUNE 16, 1896,**

At TEN for ELEVEN o'clock precisely, the

*ENTIRE CONTENTS OF THE ABOVE WORKS.*

Comprising: 25-H.P. SEMI-PORTABLE UNDERTYPE ENGINE, by Robey and Co. 10-H.P. LOCO. BOILER, by Marshall, Sons and Co. 20-H.P. HIGH SPEED ENGINE, by Bellis and Co. Twenty Screw-Cutting and other Lathes, from 4 to 19in. centres. Boring, Drilling, Planing, Slotting, Sawing, Milling, Punching and Shaping Machines, 7-ton Overhead Crane, Gauges, Stocks and Dies, Lathe and other tools, Belting, Shafting, Pulleys, &c. CONTENTS OF BRASS FOUNDRY. Also the VALUABLE ELECTRICAL PLANT, comprising Dynamos, Motors, Volt and Ammeters, Galvanometers, Wheatstone Bridges, Meters, Resistances, Switches, 15 miles of Vulcanised Cable, Telephones, Cast Iron Poles, Stays, Standards, Insulators, &c. Also the OFFICE FURNITURE, including two Safes, Typewriter, Desk, Tables, &c.

On view day preceding and morning of Sale. Admission by Catalogue only, which may be obtained from the Auctioneers, PERCY HUDDLESTON & CO., 72, Finsbury Pavement, LONDON, E.C.; 20, Chapel Works, LIVERPOOL; and 47, Grand Parade, BRIGHTON.

**TENDERS INVITED.**

CITY OF LEEDS.

TO ELECTRICAL ENGINEERS, CONTRACTORS AND OTHERS:—

The COUNCIL require TENDERS for an ELECTRICAL INSTALLATION sufficient for the working by the overhead system of haulage, a double track of Tramway seven miles long. The work will be divided into the following Contracts:—

1. POLES for supporting Trolley Wire.
2. UNDERGROUND CONDUITS and CONDUCTORS.
3. TROLLEY WIRE and attachments.
4. MOTOR CARS.
5. ACCUMULATORS and SWITCHES.
6. STEAM ENGINES.
7. DYNAMOS, SWITCHBOARDS and ACCESSORIES.

Tenders endorsed with the number of the contract must be sent in, addressed to the Town Clerk, Town Hall, Leeds, not later than JUNE 22nd next.

Particulars, plans and forms of Tender may be had (on payment of a deposit of £2 2s. for each contract, which will be returned on receipt of a bonâ fide Tender) from the City Engineer, Municipal Buildings, Leeds, or from

Dr. JOHN HOPKINSON, F.R.S.,
5, Victoria-street, Westminster, S.W.

THE CORPORATION OF CARDIFF are prepared to receive TENDERS for the CONSTRUCTION, SUPPLY, DELIVERY and FIXING of an EVAPORATIVE CONDENSER and CONCENTRIC CABLES.

Specifications may be obtained on application to Mr. W. Harpur, M.I.C.E., Borough Engineer, Town Hall, Cardiff, on and after Thursday, June 11th.

Sealed Tenders, addressed to me, and endorsed "Tenders for Electricity Works," must be left at my office, on or before Thursday, June 25th.

A fee of one guinea will be charged for a copy of either of the specifications, which will be refunded on the return of the specification, accompanied by a bonâ fide tender. The lowest or any tender will not necessarily be accepted.

By Order,
J. L. WHEATLEY, Town Clerk.

Town Hall, Cardiff, May, 1896.

A COLONIAL FIRM with OFFICES and WAREHOUSES in NEW ZEALAND and AGENCIES thoughout AUSTRALASIA, is open to REPRESENT a few good ENGLISH and CONTINENTAL HOUSES in ELECTRICAL MACHINERY and SUPPLIES (Mining Machinery preferred).

TRAVELLERS CONSTANTLY AT WORK.

*(Sole Agencies only accepted.)*

Address:
HADLEY & CO., Auckland, New Zealand.

THE

**BRITISH ELECTRIC TRACTION (PIONEER) CO.,**

LIMITED.

**1 and 2, GREAT WINCHESTER STREET, LONDON, E.C.**

*Chairman*—Sir CHARLES RIVERS WILSON, G.C.M.G., C.B.

This Company has been formed to DEVELOP ELECTRIC TRACTION in the United Kingdom and elsewhere, on the most approved methods and according to the requirements of each locality.

Address communications E. GARCKE, Managing Director

TO EMPLOYERS, COMPANY DIRECTORS, &c.

**THE LAW GUARANTEE & TRUST SOCIETY**
